CONFERENCE PROCEEDINGS

HUFLIT INTESOL INTERNATIONAL CONFERENCE 2026

Towards English as a Second Language in Vietnam: Pedagogical, Policy, and Practice Perspectives

07 August 2026 HUFLIT

STEERING COMMITTEE

1) Dr. Nguyen Anh Tuan - Vice-Chairman of Ho Chi Minh City University of Foreign Languages - Information Technology (HUFLIT).
2) Asc. Prof. Dr. Tran Manh Ha - President of HUFLIT.
3) Asc. Prof. Dr. Nguyen Ngoc Vu - Vice President of HUFLIT.
4) Dr. Nguyen Thuy Hong Van - Managing Director of Veducon, Director of INTESOL Vietnam.

ORGANIZING COMMITTEE

No.	Fullname	Title - Organaztion	Position in the Organizing Committee
1	Dr. Nguyen Anh Tuan	Vice-Chairman of HUFLIT Council	Chairman
2	Asc. Prof. Dr. Tran Manh Ha	President, HUFLIT	Deputy Chairman
3	Asc. Prof. Dr. Nguyen Ngoc Vu	Vice President, Director of TARI, HUFLIT	Permanent Deputy Chairman
4	Dr. Nguyen Thuy Hong Van	Managing Director of Veducon, Director of INTESOL Vietnam	Deputy Chairman
5	Asc. Prof. Dr. Nguyen Thanh Binh	Deputy Head of Department of Postgraduate Education - Science and Technology, HUFLIT	Permanent Member
6	Ms. Lương Thị Hồng Cẩm	Head of Communications - Public Relations, Head of Marketing Department at Veducon & Intesol Vietnam	Member
7	Dr. Thai Thi Cam Trang	Vice Director of EDC, Hanoi National University of Education	Member
8	Dr. Do Thi Phuong Mai	Head of the English Language Department - Faculty of English, Academic Director of EDC, HNUE	Member
9	Asc. Prof. Dr. Tran Van Lang	Head of Department of Science Journal, HUFLIT	Member
10	Bui Thi Thanh Truc, M.A.	Dean of Faculty of Foreign Languages, HUFLIT	Member
11	Pham Phuc Huy, MBA.	Head of Department of Planning and Finance, HUFLIT	Member
12	Nguyen Thi Thieu, MAFM.	Head of Department of External Relations, HUFLIT	Member
13	Nguyen Duy Trung, MBA.	Deputy Director of Center of Communications - Event Management, HUFLIT	Member

14	Nguyen Quoc Hung, MHrm.	Head of Department of Human Resources and Administrative Affairs, HUFLIT	Member
15	Huynh Thi Nhi, M.A.	Head of Department of Facilities Purchasing, HUFLIT	Member
16	Mr. Nguyen Minh Son	Director of Center for Facilities Operations, HUFLIT	Member
17	Dinh Hong Van, MBA.	Head of Department of Student Affairs, HUFLIT	Member
18	Dang Quoc Tuan, MBA	Director of Center of Information Technology & Data, HUFLIT	Member

PROCEEDINGS EDITORIAL BOARD

Chair:

1) Asc. Prof. Dr. Nguyen Ngoc Vu -Vice President of HUFLIT

Committee Members:

1) Le Thi Thao, MBA. - HUFLIT
2) Mr. Tchen Van An - HUFLIT
3) Nguyen Thi My Hang, MBA. - HUFLIT

TABLE OF CONTENT

INTRODUCTION xviii

#1 The Impacts of Various Teaching Methods and Assessments Applied in Business Communication Course 19

Thái Mỹ Linh 19

#2 EVALUATING PROGRAM LEARNING OUTCOME CHIEVEMENT THROUGH A DATA-INFORMED OUTCOME-BASED EDUCATION APPROACH: EVIDENCE FROM ENGLISH-MAJORED UNDERGRADUATES AT HUFLIT UNIVERSITY 36

Tran Trung Hieu , Tran Kim Tuyen 36

#3 Transinterpretation Pedagogy and Application of Artificial Intelligence for better motivation: Empirical Evidence from TMT Exercises 54

Nguyen Duc Chau 54

#7 Translation-majored Students' ChatGPT Usage Pattern and Translation Self-Efficacy 74

Quan Ngo, Chau Nguyen 74

#15 From Classroom to Real Life: First-Year Students' English-Speaking Use across Learning Contexts 94

Nguyen Thi Ngoc Chinh 94

#18 Exploring University Students' Use of AI Tools in Academic Writing at HUFLIT 109

Phan Ngoc Phuong Vy 109

#21 EFL-TO-ESL REPOSITIONING THROUGH TEACHER DEVELOPMENT: IMPLICATIONS FOR INTERNATIONALIZED EDUCATION AND WORKPLACES 124

Nguyễn Hưng Bình 124

INTRODUCTION

The TESOL International Conference 2026 (TIC 2026), organized by INTESOL Vietnam, VEDUCON, and Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT), continues to provide a forum for educators, researchers, and practitioners to share ideas and experiences in English language education. TIC 2026 takes place at a time when English teaching in Vietnam is changing rapidly. English is increasingly used not only as a subject of study but also as a means of communication in education, work, technology, and international exchange. This shift encourages us to rethink the traditional EFL classroom and explore more communicative and ESL-oriented approaches that connect classroom learning with real-life language use.

Artificial intelligence is another important part of this changing landscape. AI tools are creating new possibilities for teaching, learning, feedback, assessment, and independent practice. At the same time, they raise important questions about over-reliance, academic integrity, critical thinking, and the changing role of teachers. TIC 2026 provides a space to discuss these opportunities and concerns from both research and classroom perspectives.

The papers in this volume reflect these developments. They cover a wide range of topics, including AI-supported language learning, writing and speaking, translation and interpreting, learner autonomy, digital competence, assessment, teacher development, communicative teaching, authentic language use, and the transition from EFL to more ESL-oriented learning environments. What brings these studies together is a shared concern with how English can be taught and learned more effectively in a rapidly changing world. The contributions also remind us that technology alone cannot transform education. Meaningful change still depends on good pedagogy, thoughtful teachers, active learners, and learning environments that encourage genuine communication.

The Editorial Board sincerely thanks all authors, reviewers, presenters, participants, organizers, and partner institutions for their contributions to TIC 2026. We hope that these proceedings will provide useful ideas for further research, classroom practice, and professional collaboration in Vietnam and beyond. We welcome comments and feedback from researchers, educators, and readers at **tesol@huflit.edu.vn**.

EDITORIAL BOARD OF THE PROCEEDINGS

#1 The Impacts of Various Teaching Methods and Assessments Applied in Business Communication Course

Thái Mỹ Linh[1]

ABSTRACT

With globalization increasing the demand for proficient business communication, it is crucial to equip ESL learners with the skills required for professional environments. Business Communication is a compulsory subject in the Business English program at the Faculty of Foreign Languages, Ho Chi Minh City University of Foreign Languages and Information Technology. Based on student-centered approaches, task-based language teaching, and ongoing assessment, this study investigates how interactive teaching methods and these assessment strategies support students' communication proficiency, engagement, and readiness for workplace communication. The study examines students' perceptions of the course and the impacts of role-playing, case studies, task-based activities, presentations, projects, quizzes, peer assessment, and AI-enhanced learning tools. Data were collected from 155 student questionnaires and classroom observation checklists. The findings show that students strongly valued the course, with 95.4% confirming its importance for communication skill development. Interactive methods, case studies, hands-on activities, and presentations received highly positive responses, while project-based assessment and peer assessment were also perceived as useful, although they required careful management to reduce stress and improve feedback quality. Practically, the findings suggest that Business Communication courses should combine real-world tasks, structured peer feedback, and balanced assessment schedules to enhance both communication competence and learner confidence.

Keywords: Business Communication, teaching methods, evaluations, impacts

1. Introduction

Business Communication is a compulsory subject for juniors majoring in Business English at HUFLIT. This course is important because they are provided with useful knowledge such as how to communicate in the digital- age workplace, how to plan and participate in face-to-face and virtual meetings, and the techniques to use and develop expert writing. They also have the chance to practice and improve practical skills like professionalism and business etiquette skills, intercultural workplace skills. However, this course is high-pressure because they have to absorb considerable knowledge and acquire professional skills in business settings, which they almost have no experience and background knowledge before. In addition, with the immense amount of theory combined with several tasks to put the theory into practice, students feel overloaded if appropriate methods are not applied. According to the results of the studies carried out by Tajeddin (2018) and Barnett-Itzhaki (2023), a variety of innovative teaching methods, including case studies, presentations, projects and the applications of digital tools, can boost students' learning outcomes and level of engagement in all activities.

Another important thing that needs to be taken into consideration is how to design tests that can accurately and reliably evaluate students' competencies. To have an accurate evaluation of students' abilities, Asemanyi (2015) showed the importance of using a variety of assessment techniques, such as formative assessments, peer reviews, and assignments.

More recent studies also support the need for learner-centered and task-oriented approaches in higher education. Goodwin (2024) argues that student-centered teaching

[1] *Ho Chi Minh University of Foreign Languages - Information Technology, Vietnam; Email: linhtm@huflit.edu.vn*

promotes engagement, autonomy, and critical thinking, while recent work on task-based language teaching shows that authentic, goal-oriented tasks can improve learner motivation, communicative competence, and classroom participation (Huang, 2024; Mudinillah et al., 2024; Waluyo & Wangdi, 2024). These findings are particularly relevant to Business Communication because students are expected not only to understand business concepts but also to perform realistic communication tasks such as meetings, interviews, negotiations, presentations, and professional writing. Therefore, the present study responds to the practical problem of how to design teaching and assessment activities that reduce passive learning, increase participation, and prepare students for communication demands in future workplaces.

From the challenges mentioned above, the author applied various methods of teaching as well as testing to keep students motivated and help them achieve their goals.

2. Literature Review

The field of business communication education has come up with remarkable innovations including the integration of diverse teaching approaches and evaluation methods. These innovations have occurred thanks to the continuous development of technology, which contributes greatly to enhance students' involvement, facilitate their learning process, and equip themselves for the professional career path in the future.

❖ Teaching Methods and Assessment Strategies

Various teaching methods have been applied to improve the effectiveness of these courses. Interactive lectures, projects, presentations, case studies, etc., are among the most outstanding approaches. Research by Berry (2013) highlights the impacts of technology on teaching business communication, emphasizing the need for strategies that align with a culturally diverse audience. The use of social media platforms and collaborative tools has been shown to create a more dynamic and participatory learning environment, fostering more engagement and practical skill development. Additionally, Çelik and Alpan (2023) found that innovative teaching methods can improve certain aspects of student development.

Assessment methods by to role in evaluating and improving students' proficiency. To provide accurate evaluations and meaningful feedback, effective assessment tools must uphold the principles of fairness, validity, and reliability. Furthermore, incorporating a variety of assessment approaches enhances the learning experience by offering students multiple opportunities to showcase their skills. This not only accurately evaluates students' performance but also encourages their continuous improvement and effort to make progress.

➢ Project-Based Learning

The concept of learning through projects is not new and is increasingly applied in educational institutions around the world. It is undeniable that projects play a vital role in assessing and developing students' teamwork, problem- solving, and interpersonal skills. By replicating real working environments with work-related issues, these projects provide students with opportunities to engage in group work to fulfil the tasks. Asemanyi (2015) noted that group projects help students tackle more complex problems, assign roles and responsibilities, and share diverse viewpoint- skills that are essential in the workplace. Additionally, group projects have been shown to enhance students' time management skills, critical thinking abilities, and deepen their understanding through discussions. According to Yuliansyah & Ayu (2021), in language teaching, project-based tasks can yield tangible products such as presentations or creative products. Solomon (2003) demonstrated that project-based learning requires learners to work together to find solutions to challenging problems that are realistic

and based on the curriculum. Accordingly, the value of project-based tasks lies not only in the final product but also in the process of achieving the final goal (Kerimkulova et al., 2016).

- **Task-based language teaching**

According to Larsen-Freeman and Anderson (2011), tasks have a clear meaning and purpose, and learners need to communicate in a foreign language to achieve the goal. Therefore, this method can be considered to encourage learners to use a foreign language both in the classroom and in real-life contexts. Teachers must set clear goals to accelerate learning by engaging learners in various tasks with clear outcomes. This method focuses on a learner-centered approach. In addition, in lesson design, according to Anderson (2017), each learner's needs should be considered or other needs that may arise during the process of receiving the assigned task. Therefore, not only learning goals but also learning opportunities can be created.

In this study, task-based language teaching was operationalized through job-search tasks, mock interviews, negotiation role-plays, professional email writing, CV and cover-letter preparation, and case-based problem-solving activities. These tasks were later reflected in the results through students' responses to interactive teaching methods, hands-on activities, presentations, and project-based assessments. Therefore, the TBLT framework is not treated as a separate theory but is embedded in the course activities that required students to use English to complete realistic business communication tasks.

- **Simulations**

Simulations are forms of active learning experiences and interactive activities that create realistic scenarios, allowing students to apply language skills in a controlled environment (Lean et al., 2006). Research by Johnson et al. (2018) demonstrates that role-playing activities improve learners' communication skills, empathy, and adaptability. Simulations, such as virtual sales environments, allow students to practice without real-world consequences.

- **Peer-reviewing tasks**

Research has demonstrated that peer-reviewing helps students develop motivation and confidence in the learning process, thereby significantly improving learning outcomes. Research by Hojeij and Baroudi (2018) examined the impact of peer-reviewing on student motivation and engagement. The results showed that learners expressed positive attitudes towards peer feedback. Furthermore, students who participated in peer feedback received several benefits such as self-reflective thinking skills, problem solving and critical thinking, development of learner autonomy, promotion of self-regulation in learning and development of social skills (Hansen & Liu, 2002). Involving students in the assessment process through peer evaluations enhances their critical thinking skills and provides diverse feedback. This method encourages student responsibility and active participation in learning. According to Boon (2018), peer assessments offer varied feedback and promote critical evaluation skills, fostering student accountability and active learning. Peer evaluations have been shown to improve students' understanding of success criteria, increase their engagement in the learning process, and develop their interpersonal skills. Additionally, peer evaluations create a positive classroom environment where students can assess their own and their peers' work, leading to better learning outcomes.

- **Presentations:**

In educational contexts, oral presentations are now a common way to assess a variety of student competencies. Both verbal and nonverbal communication skills are essential for success in the workplace, and this approach is especially good at evaluating them. Nadolski et

al. (2021) highlight the value of oral presentations as an assessment tool for developing and evaluating students' presentation competence. Their study found that a well-designed formative assessment method using analytic rubrics significantly improved students' oral presentation performance. Oral presentations require students to organize and deliver messages effectively while demonstrating skills such as clarity, structure, vocal delivery, and non-verbal communication. These skills are particularly relevant to professional communication, where individuals need to present information clearly and persuasively to an audience.

- **Case Studies:**

By analyzing and presenting case studies, students can bridge the gap between theoretical knowledge and real-world business scenarios. This method not only assesses their oral and written communication skills but also enhances their critical thinking and problem-solving abilities. Asemanyi (2015) highlighted that case studies are an effective way to connect academic concepts with practical application. Through this approach, students improve their ability to tackle real business challenges, thereby honing their critical thinking and problem-solving skills. Additionally, presenting their analysis and solutions clearly and persuasively helps evaluate their communication skills. Case studies provide a practical learning experience, equipping students with tactical knowledge and skills that are directly applicable to their future careers.

- **Innovative methods applied during the course**

The student-centered approaches were applied during the course. Students were required to work in groups of 5 to 6, each of which was responsible for a project to design a training program to improve intercultural communication within an international company. The project needs to cover sessions on the significance of cultural identities, communication styles, etiquettes and taboos, cultural norms and values and conflict resolution. Each group would choose a country to focus on providing deep knowledge with illustrations like clips, short movies, etc.,

Task-based activities were designed to provide students with opportunities to practice. Students were asked to search LinkedIn to get information about job vacancies and choose the one that is most suitable for them. Then they had to conduct and participate in mock interviews. Based on the theoretical knowledge about low-context and high-context culture, they had to apply the principles of communication styles in convincing the interviewers. They also engaged in role-playing exercises to practice negotiation skills, focusing on persuasive communication, active listening, and finding mutually beneficial solutions. They were also assigned with various writing exercises: complete their own CV and cover letter, draft professional emails for various business situations.

The third task is presentations. Students prepared and delivered presentations on hot business-related topics like how businesses can use social media platforms to reach their potential customers and react in the center of a scandal.

Additionally, related to case studies, students were required to analyze a real-life business crisis. They needed to read a lot and choose one case that impressed them in terms of its impact. They had to evaluate the company's communication strategy, identify what was done well, and suggest improvements. Another topic for case study is about the success or failure of a company's customer service communication. Students analyzed the communication methods used, the results, and suggested the best practices. One last option is investigating a successful or unsuccessful marketing campaign. Students discuss the communication strategies employed, the target audience, and the campaign's impact.

After the course, the researcher would like to evaluate the significance of the course from the students' point of view as well as the impacts of various teaching methods and evaluations. Three questions were raised:

Research Questions

1. Is it really necessary to include Business Communication in the curriculum?
2. How do different teaching methods impact student engagement and learning outcomes in business communication courses?
3. What are the effects of various assessment strategies on the development of business communication skills?

3. Methods

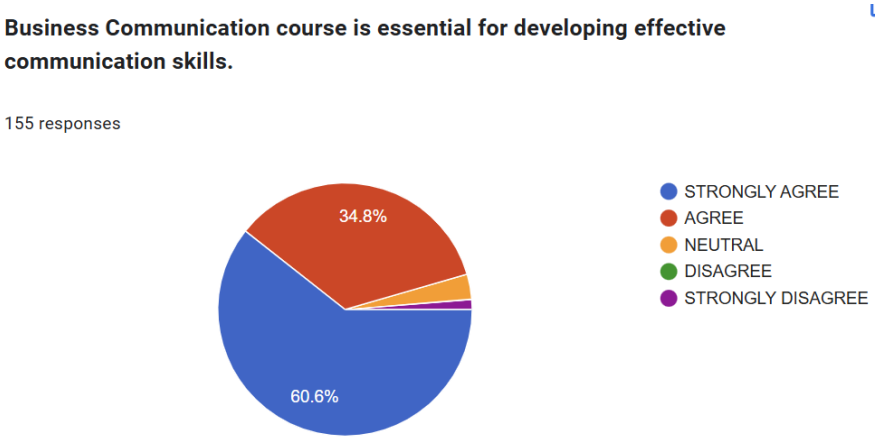
Pedagogical Setting & Participants

The survey was conducted in five Business Communication classes that the researcher oversaw teaching in the first semester of the school year 2024-2025. The learners were third-year students majoring in Business English, Faculty of Foreign Languages, HUFLIT. In previous courses, students had studied compulsory subjects such as Business English, Office Communication, Negotiation Skills, and Introduction to Management. These subjects equipped students with specialized vocabulary, knowledge and skills in reading and understanding business-related documents, drafting correspondence in business transactions, presenting on specialized topics, etc. 155 out of 208 students in five classes completed the questionnaire.

Design of the Study

A mixed-method strategy was used by the researcher. The questionnaire was designed including five scales, ranging from strongly agree to strongly disagree, from 1 to 5 respectively. It consisted of three sections: the significance of the course, the impacts of various teaching methods and the students' feedback on the necessity of various evaluation forms. It was designed in Google form and sent to students to the system of Moodle of the university. The researcher asked the students to complete the questionnaire to collect quantitative information. The qualitative component was conducted through a structured classroom observation checklist used weekly during the course. The checklist focused on observable indicators such as participation level, willingness to speak, teamwork, confidence in presentations, response to peer feedback, anxiety during assessments, and ability to complete communicative tasks. After each class, the researcher recorded short field notes beside each checklist item. In addition, the researcher also carried out classroom observations to have a better understanding of how students react to the innovated methods. During the course, students' attitudes, behaviors, and participation in each activity were noted down in the observation checklist weekly.

Data collection & analysis



The researcher created the questionnaire on Google Forms and sent it on Moodle in the last week of the semester. This was to ensure that students had sufficient time and experience to evaluate the course and provide reliable feedback. They also did not need to worry about the lecturer's reaction when giving negative responses. The researcher had one week to collect the data. Quantitative survey data were summarized by frequency and percentage to identify students' overall perceptions of each teaching method and assessment form. Qualitative observation notes were analyzed through a simple thematic coding process. First, the researcher reviewed weekly notes several times to become familiar with recurring patterns. Second, similar observations were coded, such as "active participation," "improved confidence,"

"assessment anxiety," "teamwork difficulty," and "quality of peer feedback." Third, these codes were grouped into broader themes that corresponded to the research questions: course significance, teaching-method impact, and assessment impact. The qualitative themes were then used to explain and support the quantitative survey results.

4. Results/Findings

Figure 1

The importance of Business Communication courses in developing effective communication skills.

An overwhelming majority of students acknowledged the importance of this course, as seen in Figure 1. 34.8% of students agreed and 60.6% strongly agreed that the course is essential to improve their communication abilities. This means that an overall number 95.4% of the students appreciated the course's beneficial influence on their competence for effective communication.

Only a tiny proportion of students had neutral viewpoints. Compared to the overwhelming positive responses, this group was not significant. Only two out of 155 students—or just 1.3%—strongly disagreed with the course's importance.

The theoretical knowledge and practical skills that the students gained from this course are obviously advantageous. The overwhelming positive feedback asserts that the course is greatly beneficial to improving students' communication skills.

Figure 2

Interactive teaching methods (group discussions, role-playing) enhance students' engagement.

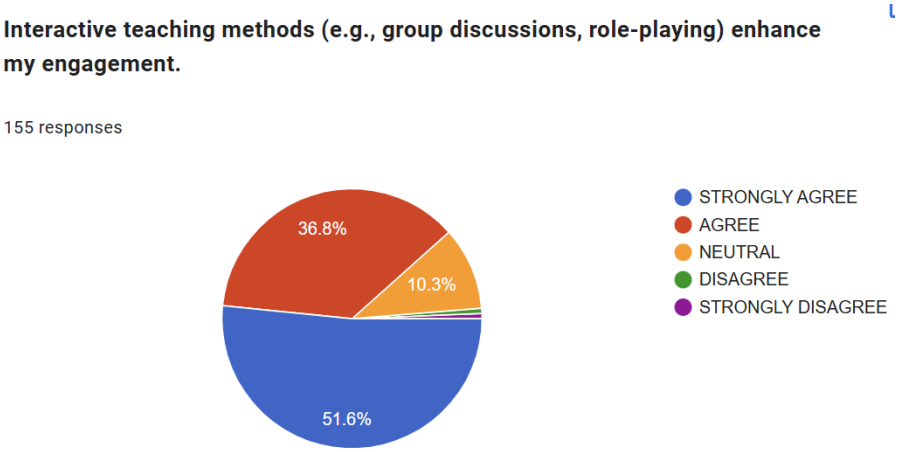


Figure 2 illustrates how various interactive teaching techniques can contribute to increase students' engagement in the learning process. According to the results, approximately 90% of respondents had extremely positive feedback on the application of diverse learner-centered methods used in the course. This significant proportion shows that students highly valued the effectiveness that these interactive approaches- including role-playing, group debates, and other collaborative tasks- bring to help them improve.

A tiny percentage of students, only 1 out of 155, or 0.6%, strongly disagreed with the effectiveness of these approaches. Additionally, the same percentage of students disagreed, emphasizing the positive comments outweigh the negative ones. The data highlights the effectiveness of applying interactive teaching methods.

In addition, the notes in the researcher's observation checklists during the 12-week period provide supportive evidence for these conclusions. It was noticeable throughout this period that the great majority of students engaged actively in all the interactive tasks and activities that were organized every week in class. The high degree of participation shows that students were not only interested in these approaches but also appreciated that these methods were truly helpful for their education and future career. Thanks to the application of these methods, a more dynamic and captivating learning environment was established. As a result, students were more engaged in the learning process, which improved their motivation in the process of exploring knowledge.

Figure 3

The roles of case studies and real-world examples

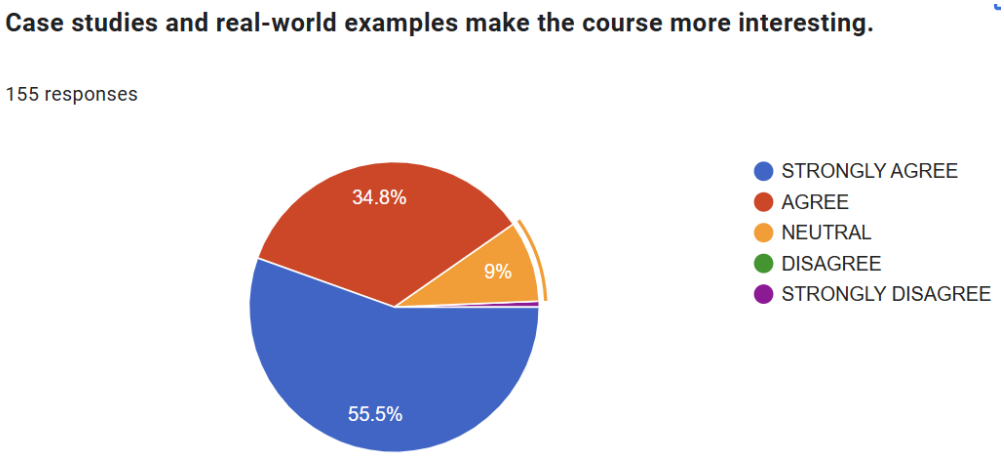

Figure 3 demonstrates the importance of case studies and real-world examples in drawing and maintaining students' attention during the course. According to the data, an overwhelming majority of respondents felt satisfied with the analysis of case studies and business-related examples. 34.8% of students agreed and 55.5% strongly agreed that this was very successful at maintaining their interest. In other words, 90.3% of students had positive feedback about the use of case studies and real-world examples in the curriculum.

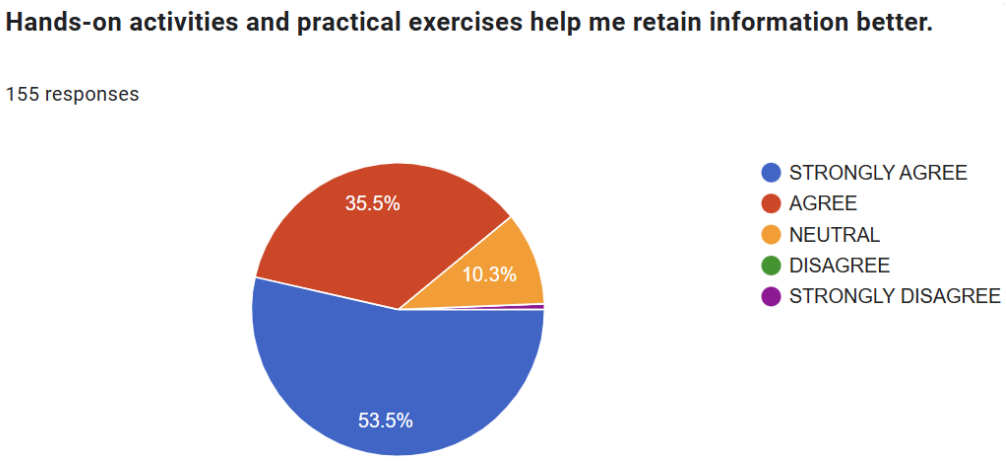
Additionally, according to the notes from the observation checklists, the researcher realized that when students participated in discussions and debates based on case studies, they became very enthusiastic and interested. These tasks promoted critical thinking and active engagement. Students were able to apply theory to real-world situations, which motivated them in the process of exploring knowledge.



Only 9% of students expressed no opinion about how successful case studies and real-world examples are. This proportion can be implied that these methods could be improved and modified further to better cater to the diverse linguistic backgrounds and proficiency levels of every learner. A tiny minority, 0.6% of students (1 out of 155) strongly disagreed that case studies and real-world examples were helpful, which is not remarkable.

The results show that case studies and real-world examples play a crucial role in drawing in and retaining students' attention. The overwhelmingly positive responses demonstrate how effective these methods are in creating an engaging and motivating learning environment.

To sum up, findings from Figure 3 and notes from the observation checklists clearly show that using case studies and real-world examples is a very good way to grab students' interest and improve their involvement in the course. In addition to making learning more fun, these techniques greatly enhance critical thinking and problem-solving abilities, which are crucial for students' success in university and the future career paths as well.

Figure 4

The roles of hands-on activities and practical exercises in helping students retain information

It is evident from Figure 4 that a sizable majority of students-89% acknowledged the value of practical exercises and hands-on activities in aiding in their memory retention. Because the course gives students a thorough understanding of business topics, covering a wide range of concepts, theories, principles, and more, it would be very difficult for students to remember and apply the knowledge they have learned if proper teaching techniques were not used. These exercises and hands on activities offer students the opportunity to engage with theoretical concepts more practically, enhancing their ability to retain and apply knowledge in real-life situations. This strategy greatly differs from conventional lecture-based techniques, which make students passively learn new knowledge and as a result hinder them from remembering new business concepts. Furthermore, only a small minority were unaware of the usefulness of these techniques. While the neutral responses indicate some variation in learning preferences, the overall positive impact of the different approaches is clear.

The results of on-going exams and assessments provide more evidence of the efficacy of various techniques. Based on their results in these assessments, it can be concluded that students' comprehension ability and memory of the subject matter have clearly been strengthened by the frequent inclusion of these exercises and hands-on activities. In summary,

the result and evidence from on-going evaluations highlight the significant role of practical exercises and hand-on activities in the learning process. These methods not only enhance students' ability to retain information but also prepare them to apply it in real world situations.

Figure 5

The application of presentations

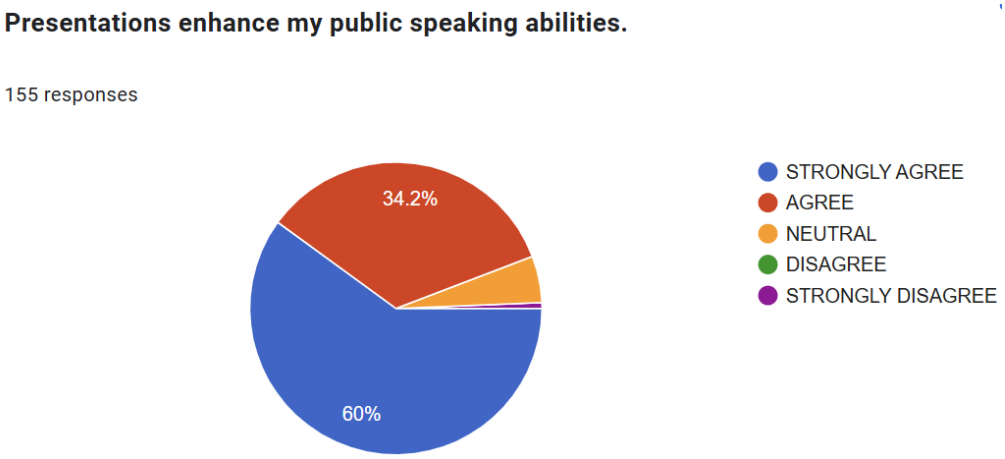


Figure 5 demonstrates how delivering presentations can enhance students' confidence and their ability to speak in public. Presentations clearly play a crucial role in building their self- esteem, as reflected by 34.2% of students who agreed and the 60% strongly agreed that presentations greatly improve this challenging skill. This indicates that an overwhelming number of students overall acknowledged the beneficial effects of presentations on their ability to express ideas in public. These conclusions are further supported by the observations recorded in the checklists. According to the notes, about 70% of students expressed their extreme anxiety when they had to give a presentation for the first time. This anxiety showed out in several ways, including stuttering, repeating sentences or even phrases several times, and completely avoiding eye contact with the audience. Furthermore, a lot of students found it difficult to engage with their audience, which is a typical problem for those who are exposed to public speaking the first time.

But as the course went on, there was a remarkable change. Students became more and more confident in their next presentations. They began to communicate more smoothly, interact with their audience more effectively, and maintain eye contact. The continuous practice and feedback they received from their lecturers directly contributed to their increased professionalism and confidence as presenters. Additionally, only 5.2% of students expressed neutral views regarding the effectiveness of presentations. It can be explained that these students could not overcome the tension and stress when delivering a speech and 12 weeks seems not enough for them to struggle.

Just 0.6% of students disagreed that presentations were effective. The positive feedback outnumbered the negative ones, which demonstrates the importance of presentations in helping students become more confident and proficient speakers.

In summary, the results shown in Figure 5 and the observational data clearly indicate that giving presentations is an effective way for boosting students' confidence and communication skills in public. Students gain more experience and practise, their initial discomfort gradually diminished, leading to improved performance and greater professionalism. The widespread agreement among students on the benefits of presentations

underscores their importance in the curriculum and establishes them as a key tool for developing essential communication skills.

Figure 6

Project-based assessments

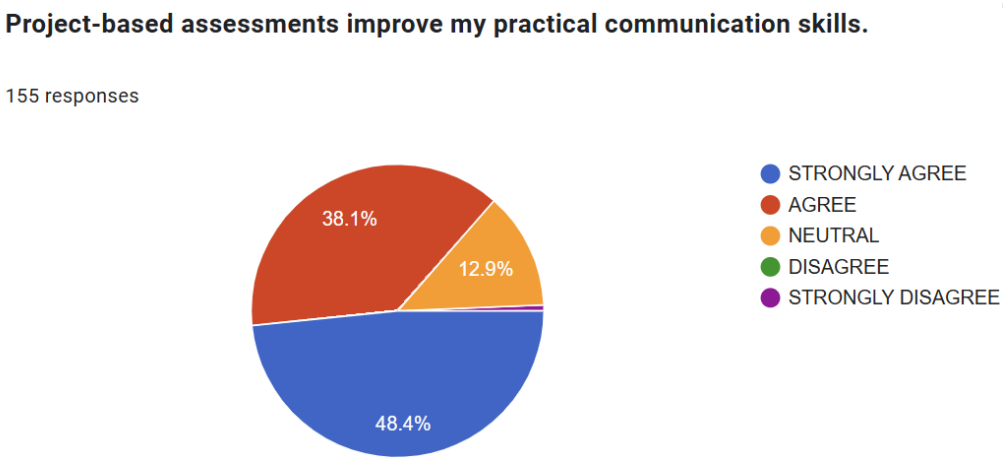

Figure 6 shows students' feedback about project-based assessments. 38.1% of the students agreed, and nearly half strongly agreed, that project-based evaluations greatly improve their communication abilities. This indicates that an overwhelming proportion 86.5% of students in all acknowledged the importance of project-based evaluations in improving their capacity for clear communication. It can be concluded that project-based learning is an effective method for students at this stage of academic career.

12.9% of students expressed no opinion about the benefits of project-based assessments in helping them improve their skill. Based on the notes in the observation checklists, the researcher realized that some students experienced stress when working on projects for a variety of reasons. The fact that group members had different schedules can be challenging to find a time fitting everyone. Moreover, unavoidable conflicts arose, impeded the project's advancement and increased their stress levels. Another important reason is that some students might not have good time management skills and interpersonal skills needed to successfully complete group projects. These skills are essential for completing the projects.

Despite these challenges, it can be said that the project-based approach is still the best option for this subject at the highest level of university education. Instead of relying on the lecturer, students are required to take part in projects and familiarize themselves with the tasks to be fulfilled. By doing this, they are prepared for their future professional employment. This approach gets them ready for the realities of the corporate world, where projects are becoming more essential.

In conclusion, project-based evaluations have a lot of benefits in terms of skill development and preparation for real-world business. Through encouraging self-reliance, teamwork, and clear communication, project-based learning gives students the skills they need to be successful in university and in the workplace.

Figure 7

The effectiveness of frequent quizzes and tests

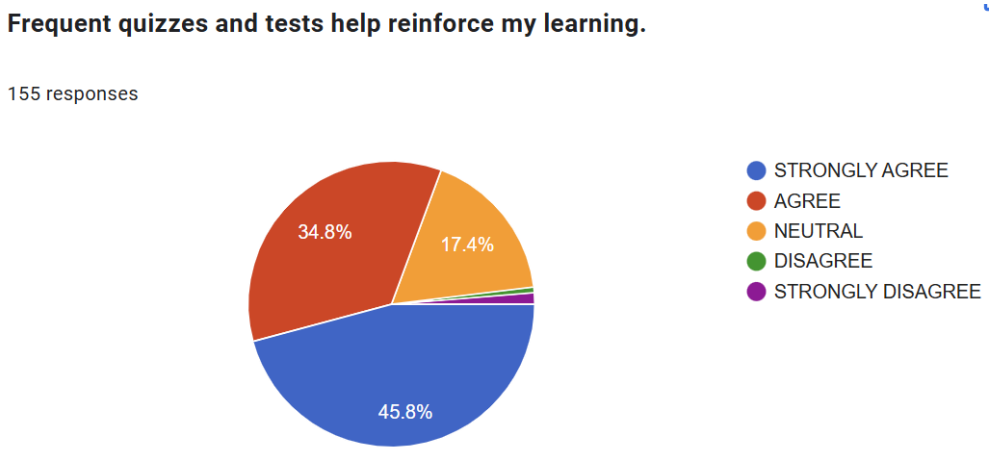

Figure 7 shows the students' opinions about the implementation of frequent quizzes and tests in class. According to the results, 45.8% and 34.8% of students respectively strongly agreed and agreed that regular tests and quizzes aid in their learning. They acknowledged the advantages of frequent evaluations. According to the notes from the researcher's checklist, when students received ongoing feedback on their progress from these constant assessments, they knew which areas needed improving. As a result, there will be fewer mistakes or weaknesses in the next tests.

It is noticeable that a comparatively high proportion 17.4% of students had no idea about the benefits of frequent tests and quizzes. According to the notes from the checklists, some students confirmed that they experienced tension and anxiety when they had to take tests and quizzes on a regular basis. This feedback is important because it emphasizes how frequent assessments might affect students in a negative and unexpected way.

According to the requirements in the course detailed outline, at least three mini-tests must be taken throughout a 12-week period. The purpose of this frequent evaluation is to ensure that students can consistently track their progress and identify their weakness. However, this puts a lot of strain on the students and the lecturer as well. The pressure to perform well on these tests led to increased stress and anxiety. This has an adverse effect on the students' learning process. Students must continuously study for and do well on these tests, and lecturers must constantly create and grade these tests. To tackle the issue, teachers must consider the different forms of these tests to reduce the pressure on students.

In conclusion, although the data shows that most students recognize the benefits of regular tests and quizzes, the comments about stress and the sizeable percentage of ambivalent answers emphasize the necessity for a flexible strategy. Teachers should try to create tests that can effectively evaluate the students' skills and reduce their stress as well.

Figure 8

The role of peer assessment in helping students improve

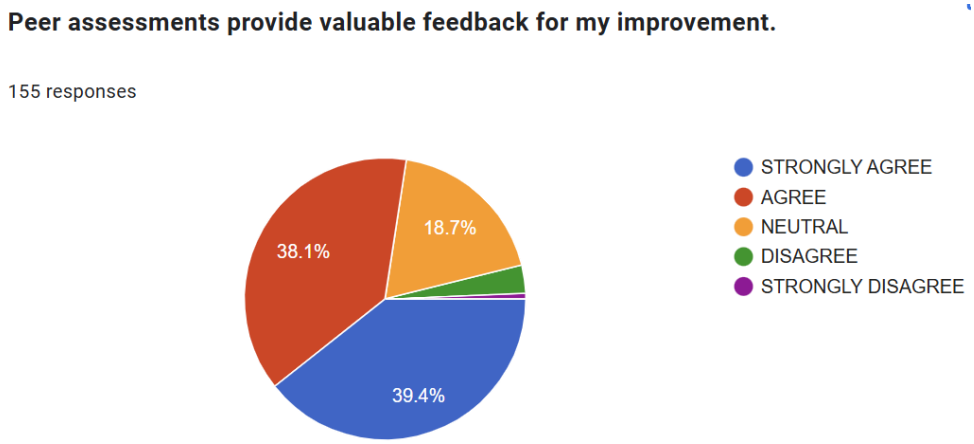

Figure 8 illustrates students' opinions about their peers' feedback in helping them improve their skills.

According to the results, the percentages of respondents who strongly agreed and agreed that peer assessments much enhance their improvement were approximately the same, accounting for 39.4% and 38.1%, respectively. Noticeably, 18.7% of respondents had neutral ideas about how helpful peer evaluations are. The highly subjective remarks and criticism that some students got on their friends' work can be interpreted in conjunction with the observation checklist notes. Despite of the fact that many of the remarks were helpful and constructive, some feedback was not objective, based on prejudice and emotional judgement which might have made some students not value their peer assessments. These results are supported by the notes from the observation checklists, which show that constructive and justified feedback contributes greatly to the improvement as well as the motivation of the students. They frankly showed that they did not appreciate or value their friends' comments if it is opinionated or prejudiced. Therefore, it is crucial to guide students on how to provide their peers with unbiased, helpful, and constructive feedback. It is advisable to provide them with a range of criteria to evaluate their peers in various tasks. Only 3.2% of students didn't agree that peer evaluations are valuable for them in developing their skills.

Generally, positive responses about peer assessments outnumbered the negative ones, which highlights the potential of this as a valuable teaching tool. Peer assessments promote collaborative learning and a deeper understanding of the theory by encouraging students to critically analyze one another's work. Peer assessments strengthen students' ability to evaluate the work of others and simultaneously they learn a lot from their peers thanks to the observation process.

In summary, the results and data from the observational notes show that peer evaluations are crucial for assisting students in developing their knowledge and abilities. The overwhelmingly positive responses indicate that peer assessments are an indispensable part of the learning process. To improve peer assessments' efficacy and guarantee that every student gains from this collaborative learning strategy, it is necessary to tackle the problems with feedback quality.

5. Discussion

According to this research, most students- 95.4% positive responses all together- agreed strongly or agreed that the course plays a vital role in improving their communication skills, which are essential for becoming employable in the competitive job market. A study by Ismail

(2011) concluded that the prospect of being employed is higher amongst graduates with a good competency of English. As a result, the students' feedback shows that being equipped with the skills and knowledge in this course, they are more confident that they will improve their employability. Another important finding is that approximately 90% of students gave favorable comments, claiming that interactive learner-centered teaching techniques like role-playing and group discussions greatly increase their involvement in all activities, which makes learning more dynamic and efficient. The results are not out of the expectation of the author and supported by the data from the checklist notes. The learner-centered methods proved to be extremely effective in gaining students' attention and interest. In addition, most students found case studies and real-world examples to be very engaging. The same number of students agreed that practical exercises and hands-on activities are crucial for long-term retention of business knowledge because they allow theoretical concepts to be applied practically. In brief, innovated approaches that focus on the students' needs are highly appreciated and contribute to increasing their level of satisfaction.

Despite of the fact that project-based tasks might be stressful, 88.1% of students acknowledged the benefits they bring. Based on the notes from the observation checklists, the researcher confirmed that students improved several skills during the process of doing the projects. They had to analyze real-world problems and brainstorm to discuss innovative solutions. Therefore, they can be more creative and motivated as well to fulfill the tasks. These projects also greatly foster teamwork and improve their interpersonal skills. They had the chances to explore the issues in depth, leading to better retention and understanding. In short, project-based evaluations are the most suitable option for senior students because they are prepared for future work.

It cannot be denied that frequent quizzes and tests create stress for students. Surprisingly, 80.6% of students felt that they were quite beneficial. It can be explained that the variety of test forms like mini tests, quizzes, presentations, projects, etc. to evaluate different skills reduces the boredom of doing tests and students recognize the benefits of these constant evaluations.

Finally, the number of students who found peer assessments to be useful was not so high, accounting for 77.5%. More than 22% of students were unhappy with their peers' comments. The writer thinks that because there were some biases in some peer evaluations and comments, nearly a quarter of students were unsatisfied.

This study supports earlier research that highlights the value of hands-on, interactive learner-centered teaching strategies. It asserts the idea that active learning techniques, such project-based learning and practical exercises, improve student interest and memory. In line with past research emphasizing the importance of communication skills in the labor market, the results support the importance of these abilities in enhancing employability. Furthermore, the study's findings about the value of peer evaluations and presentations support other studies that found similar techniques to be essential for fostering students' self-assurance and teamwork. In conclusion, the study adds to the increasing amount of data demonstrating creative and student-centered teaching strategies in higher education.

6. Conclusion

The findings from this study highlight the importance of this course to the students' employability and adaptability in the future workplace. In addition, a variety of student-centered teaching methods and innovative forms of on-going assessments have been proved to enhance their interest and motivation in learning, help them take ownership of their learning

and acquire important skills to meet the challenging demands of the labor market. From the students' perspective, these various teaching methods and evaluations, including role-playing, case studies, projects and presentations play a significant role in assisting them improve their communication proficiency and explore the knowledge in depth.

In direct response to the three research questions, the findings confirm that Business Communication is perceived as necessary in the curriculum because it supports students' employability, confidence, and readiness for workplace communication. The findings also show that learner-centered teaching methods, especially role-playing, case studies, task-based activities, presentations, and practical exercises, increased students' engagement and helped them connect theory with real-life business contexts. Finally, the results indicate that assessment strategies such as projects, quizzes, presentations, and peer assessment contributed to skill development when they were clearly structured, balanced in workload, and supported by constructive feedback. These conclusions demonstrate a clear alignment between the research questions, survey findings, and classroom observation themes.

One thing that needs to be taken into consideration is that although regular examinations and quizzes are good for consolidating knowledge, they should be balanced to prevent unnecessary stress for students. During 12-week semester, 3 compulsory tests and a project seem to be a burden for students because they must meet deadlines in other courses. I suggest that there should be some modification in the course detail outline so that tests are not stressful for both the test maker and test takers.

Another important thing is that even though peer evaluations are a good solution for teachers as they save time and for students as they get valuable feedback from their peers, they must be carefully managed to guarantee helpful and constructive criticism. From my point of view, to achieve this goal, the teacher should provide students with a guideline in which there are specific requirements and criteria to evaluate their peers' performance.

Despite offering insightful information, the study had a few drawbacks. Only 155 students took part in the survey, which might not accurately reflect all the students majoring in Business English.

A larger and more varied sample size should be considered in future studies to improve the findings' generalizability and reliability. Furthermore, investigating how well these teaching strategies work in more classes would support and broaden the conclusions.

7. Acknowledgments

My sincere appreciation goes out to the following people and institutions for their vital contributions to this study:

The Department of Business English, for supporting me to carry out this research. Their assistance was essential in making the research efforts possible.

The students who took part in the study, whose eager participation and candid criticism were crucial to its success. My results and conclusions were based on their contributions.

For their helpful critiques and support throughout the several phases of this study, I am grateful to my peers and colleagues. Their suggestions enabled me to increase the study's overall quality and hone my methodology.

Thank you to family and friends for your steadfast understanding and support during the study process. Their patience and support were crucial.

I would like to express my sincere gratitude to everyone who helped with this study, and I recognize that without their combined efforts, it would not have been possible.

Biodata

The researcher is a full- time lecturer in Ho Chi Minh city University of Foreign languages and Information technology. She has nearly 30 years' experience teaching Business English. She's interested in methodology, language testing and related fields. She regularly attends conferences to learn from other researchers.

#2 EVALUATING PROGRAM LEARNING OUTCOME CHIEVEMENT THROUGH A DATA-INFORMED OUTCOME-BASED EDUCATION APPROACH: EVIDENCE FROM ENGLISH-MAJORED UNDERGRADUATES AT HUFLIT UNIVERSITY

Tran Trung Hieu[1] , Tran Kim Tuyen[2]

Abstract

Outcome-Based Education (OBE) has become a dominant framework for curriculum design and quality assurance in higher education. Within this framework, program learning outcomes (PLOs) serve as key indicators of students' expected competencies upon graduation. However, limited empirical evidence exists regarding how specific PLO domains contribute to students' employability readiness, particularly in English language studies programs in Vietnam. This study investigated students' perceptions of the achievement of four program learning outcomes—English language proficiency and competency, majoring-specialization competencies, digital literacy, and second foreign language competence (SFL), and examined their relationships with employability readiness. A quantitative survey was administered to 261 students enrolled in the English language studies program at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). Data were analyzed using descriptive statistics, reliability analysis, Pearson correlation, one-way ANOVA, and multiple regression analysis. The findings revealed that students generally reported positive perceptions of all PLOs and employability readiness (ER). All scales demonstrated satisfactory reliability, with Cronbach's alpha coefficients ranging from .883 to .957. Correlation analysis showed significant positive relationships between all PLO domains and employability readiness. Multiple regression analysis revealed that the four PLO domains jointly explained 59.2% of the variance in employability readiness ($R^2 = .592$, $F = 92.995$, $p < .001$). Hierarchical regression further demonstrated that the PLO variables contributed an additional 54.2% of explained variance beyond demographic and academic characteristics ($\Delta R^2 = .542$, $p < .001$), highlighting the substantial role of program learning outcomes in shaping students' ER.

Keywords: Outcome-Based Education (OBE), program learning outcomes (PLO), English Language Studies programs, employability readiness (ER), Common European Framework of Reference for Languages (CEFR)

1. INTRODUCTION

1.1 Background of the study

In recent years, higher education institutions (HEI) have faced increasing pressure to prepare graduates who can meet the demands of a rapidly changing and highly competitive labor market. Beyond disciplinary knowledge, employers increasingly value graduates who possess strong communication skills, digital competence, adaptability, and professional readiness. Consequently, graduate employability has become an important indicator of higher education quality and effectiveness.

To address these expectations, many universities have adopted Outcome-Based Education (OBE), an educational approach that emphasizes the achievement of clearly defined learning outcomes. Within OBE, Program Learning Outcomes (PLOs) serve as key benchmarks for curriculum design, teaching, assessment, and quality assurance. The effectiveness of an academic program is therefore often evaluated based on the extent to which students achieve the intended learning outcomes (LOs).

In Vietnam, OBE has been widely implemented as part of ongoing higher education reforms and accreditation requirements. English Language Studies programs, in particular, are expected to equip students with a combination of language proficiency, disciplinary knowledge, digital literacy, and multilingual competencies that support their future careers. While these competencies are commonly embedded in program learning outcomes, empirical evidence regarding their contribution to employability readiness (ER) remains limited.

1.2 Research problem

Although previous studies have examined language competence, curriculum quality, and graduate employability separately, relatively few have investigated how different PLO domains collectively influence students' ER. This gap highlights the need for further research on the relationship between PLOs and ER within English language education programs.

Within this context, the English Language Studies program at Hochiminh City University of Foreign Languages – Information Technology (HUFLIT), Vietnam, provides an appropriate case for investigating outcome-based curriculum effectiveness. The program is designed according to OBE principles and incorporates multiple PLO domains, including English language proficiency and competency (PLO3), majoring-specialization competencies (PLO4), digital literacy (PLO5), and SFL competence (PLO6). While these outcomes are formally embedded in the curriculum, there is limited empirical evidence on how students perceive their attainment of these outcomes and how such perceptions relate to their overall ER.

Therefore, this study adopts a data-informed OBE approach to examine students' perceived attainment of the four key PLOs and their relationship with the ER.

1.3 Research objectives

This study aims to:

1. Examine students' perceptions of the achievement of the four key PLOs including PLO3, PLO4, PLO5 and PLO6.
2. Investigate the relationships between these four PLOs and the ER.
3. Identify the extent to which PLOs predict the ER.

1.4 Research questions

1. Research question 1: How do English-majored students perceive their attainment of the four PLOs in the English Language Studies program at HUFLIT?
2. Research question 2: Which PLO domains are perceived as the most and least developed by students?
3. Research question 3: To what extent do different PLO domains contribute to students' perceived ER?

1.5 Significance of the study

This study contributes to the growing body of researches on OBE by providing empirical evidence regarding the effectiveness of PLOs in fostering ER. The findings may assist curriculum developers, academic leaders, and quality assurance practitioners in improving educational programs and enhancing graduate outcomes.

2. Literature Review

2.1 Outcome-based education in higher education

OBE has become one of the most influential educational paradigms in higher education worldwide. According to Spady (1994), OBE emphasizes the achievement of clearly articulated learning outcomes rather than the completion of prescribed instructional content. Under this approach, curriculum design, teaching strategies, assessment methods, and quality assurance mechanisms are systematically aligned with the intended graduate competencies.

The growing adoption of OBE reflects broader shifts toward accountability, transparency, and evidence-based quality assurance in higher education. Universities are increasingly required to demonstrate that graduates possess competencies relevant to contemporary workplace demands and societal expectations. Consequently, program effectiveness is evaluated not only through academic performance but also through measurable learning outcomes and graduate success indicators.

Recent scholarship suggests that OBE contributes positively to curriculum coherence, learner-centered instruction, and continuous quality improvement. According to Biggs and Tang (2022), outcome-oriented curriculum design promotes constructive alignment among learning outcomes, teaching activities, and assessment practices, thereby enhancing students' learning experiences. Similarly, Harden (2007) argues that OBE facilitates systematic curriculum evaluation and supports institutions in meeting accreditation standards.

In Southeast Asia, OBE has become a key component of higher education reform. Universities have increasingly integrated outcome-based principles into curriculum development and assessment systems to align educational provision with international quality assurance frameworks. However, despite widespread implementation, empirical studies examining how specific PLOs contribute to graduate readiness remain relatively limited, particularly in language education programs.

2.2 Program learning outcomes and constructive alignment

PLOs constitute the cornerstone of OBE implementation. They define the knowledge, skills, attitudes, and competencies that students are expected to demonstrate upon graduation. Effective PLOs serve multiple functions, including curriculum planning, instructional alignment, assessment design, and stakeholder communication.

The theoretical foundation underlying PLO implementation is Constructive Alignment Theory (Biggs & Tang, 2022). This framework posits that meaningful learning occurs when

intended learning outcomes, teaching activities, and assessment methods are aligned. Such alignment enables students to engage in learning activities that directly support the achievement of desired competencies.

Research consistently demonstrates positive relationships between curriculum alignment and student achievement. Programs with clearly articulated and systematically assessed learning outcomes tend to report stronger academic performance, higher student satisfaction, and improved graduate outcomes. Furthermore, outcome alignment supports institutional quality assurance processes by providing measurable indicators of educational effectiveness.

Within English language education, PLOs typically encompass multiple competency domains, including linguistic proficiency, disciplinary knowledge, intercultural communication, digital literacy, and professional skills. Because language graduates increasingly work in diverse and technology-mediated environments, outcome frameworks must extend beyond language competence alone.

Additionally, according to Kennedy (2007), learning outcomes describe what learners are expected to know, understand, and be able to demonstrate upon successful completion of a programme of study. Clearly articulated learning outcomes therefore serve as the foundation for curriculum design, teaching, assessment, and quality assurance processes.

2.3 English language education, CEFR, and competency development

The Common European Framework of Reference for Languages (CEFR) has become the dominant international framework for language proficiency assessment and curriculum design. Since its introduction, CEFR has provided a common reference system for describing language ability across educational contexts.

In Vietnam, CEFR-aligned learning outcomes have been widely adopted in higher education institutions, particularly within English language programs. Universities increasingly utilize CEFR benchmarks to establish graduation requirements and evaluate language competence. This alignment enhances transparency, comparability, and international recognition of language qualifications.

Nevertheless, contemporary English language education extends beyond linguistic competence. The evolving nature of global communication and workplace practices requires graduates to possess a broader range of professional competencies. Scholars have argued that successful language graduates must integrate language proficiency with disciplinary expertise, intercultural competence, technological literacy, and lifelong learning capabilities.

Digital transformation has further expanded expectations for language professionals. The emergence of artificial intelligence, online communication platforms, and digital collaboration tools has increased the importance of technological competence within language-related professions. Consequently, many English language programs have incorporated digital literacy as a core learning outcome alongside traditional linguistic objectives.

Recent studies indicate that graduates possessing both strong language skills and digital competencies demonstrate greater adaptability and employability in contemporary labor markets. This suggests that language proficiency alone may be insufficient to ensure successful career outcomes, highlighting the need to examine the combined influence of multiple competency domains.

2.4 Graduate employability and employability readiness

Graduate employability has emerged as a central concern for higher education institutions globally. As universities face increasing pressure to demonstrate societal relevance, employability outcomes have become important indicators of educational quality and program effectiveness.

Yorke (2006) conceptualizes employability as a set of achievements, including knowledge, skills, understandings, and personal attributes that increase graduates' likelihood of obtaining employment and succeeding in their chosen professions. More recent frameworks extend this definition by emphasizing adaptability, resilience, lifelong learning, and technological competence.

The literature identifies several dimensions consistently associated with employability, comprising of professional knowledge and disciplinary expertise, communication and interpersonal skills, critical thinking and problem-solving abilities, digital literacy and technological competence, adaptability and lifelong learning capacity, and multilingual and intercultural communication skills.

For graduates of English language programs, ER represents a multidimensional construct. Employers increasingly seek graduates who can communicate effectively in English while simultaneously demonstrating professional competence, technological proficiency, and cross-cultural communication skills.

Previous studies have reported positive relationships between language proficiency and employability outcomes. However, recent evidence suggests that employability is influenced by a combination of competencies rather than a single skill domain. Graduates who possess integrated skill profiles tend to demonstrate greater workplace readiness and career adaptability.

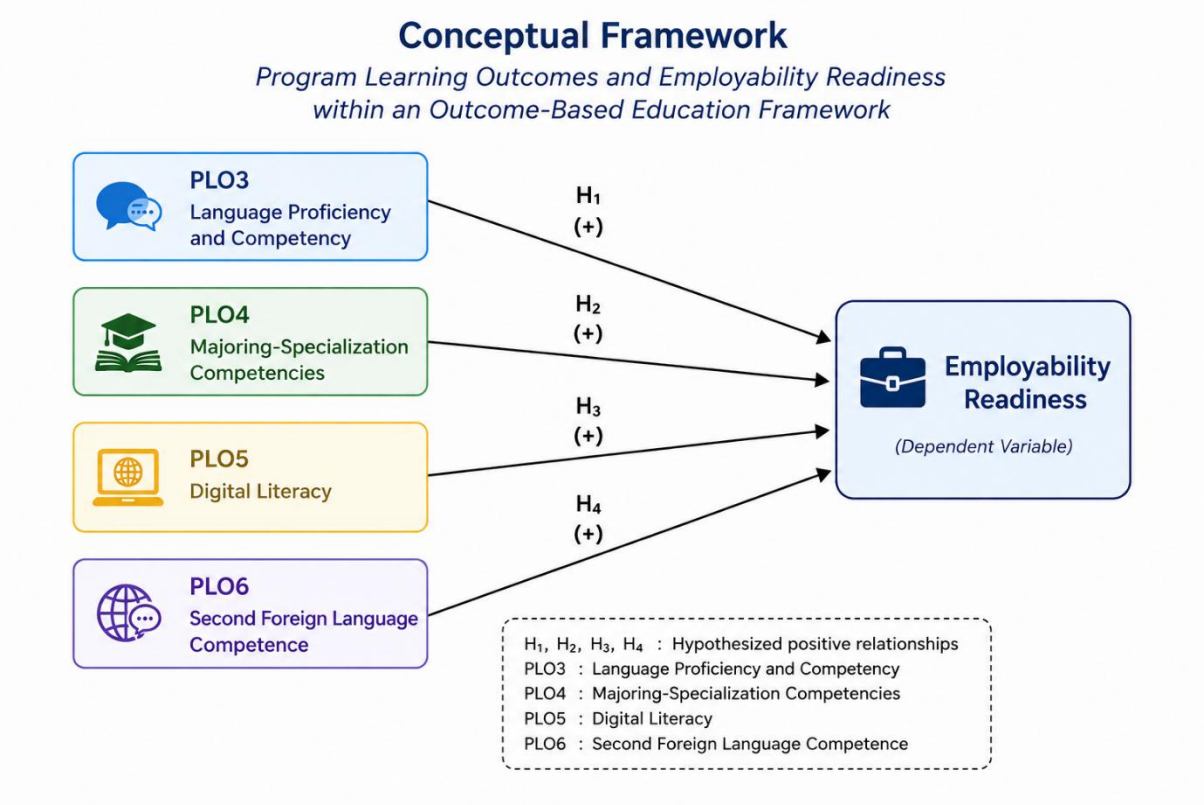
2.5 Empirical studies and research gap

A growing body of researches has examined the effectiveness of OBE implementation in higher education. Existing studies generally report positive impacts on curriculum quality, student achievement, and learning outcome attainment. However, several limitations remain evident in the literature.

First, many studies focus primarily on evaluating individual learning outcomes rather than examining the combined contribution of multiple PLO domains. Second, researches in language education frequently emphasize language proficiency while overlooking broader competencies such as digital literacy and multilingual capability. Third, empirical investigations linking OBE-based learning outcomes directly to employability readiness remain relatively scarce, particularly within Southeast Asian contexts.

Within Vietnam, researches on outcome-based curriculum evaluation have increased in recent years. Nevertheless, studies that simultaneously investigate language proficiency, disciplinary competence, digital literacy, second foreign language competence, and employability readiness are still limited. Consequently, there is insufficient evidence regarding which competency domains contribute most strongly to students' perceived ER.

To address these gaps, the present study examines four key PLO domains: language proficiency and competency (PLO3), majoring-specialization competencies (PLO4), digital literacy (PLO5), and second foreign language competence (PLO6) and investigates their relationships with the ER among English language studies students. By integrating outcome-based assessment and employability perspectives, this study contributes empirical evidence to



support data-informed curriculum evaluation and quality assurance practices in higher education.

2.6 Conceptual framework

Based on the literature reviewed, the study proposes the following conceptual framework:

Figure

Research conceptual framework

3. METHODOLOGY

3.1 Research Design

This study employed a quantitative correlational research design to investigate the relationships between the four designated PLOs and the employability readiness among English Language Studies students at HUFLIT University.

The study was grounded in the Outcome-Based Education (OBE) framework, which emphasizes the achievement of clearly defined learning outcomes and their contribution to graduate competence. Specifically, the study examined four major PLO domains:

PLO3: English language proficiency and competency;

PLO4: majoring-specialization competencies;

PLO5: digital literacy;

PLO6: second foreign language competence.

ER: employability readiness.

ER was treated as the dependent variable representing students' perceived preparedness for future employment.

A cross-sectional survey design was adopted because it allowed researchers to collect data from a large number of respondents within a relatively short period and examine statistical relationships among variables.

3.2 Research context

The study was conducted within the English Language Studies program at HUFLIT University, Vietnam, a private higher education institution that offers undergraduate and postgraduate programs in languages, business, information technology, and related disciplines.

In response to national higher education reforms and quality assurance requirements, the English Language Studies program which is revised and edited every two years has adopted an OBE framework to ensure the alignment among curriculum design, instructional practices, assessment activities, and intended PLOs. Within this framework, student learning achievement is systematically evaluated to support continuous program improvement and accreditation processes.

The program specifies four key competency domains that are expected to contribute to graduates' professional development and employability: PLO3, PLO4, PLO5, and PLO6. These competencies reflect both disciplinary requirements and the transferable skills increasingly demanded by contemporary labor markets.

As part of the program's quality assurance and curriculum evaluation efforts, regular assessments are conducted to examine students' perceptions of learning outcome attainment. Against this background, the present study investigates the extent to which students perceive achievement of the specified PLOs and examines the predictive relationships between PLO attainment and ER. The findings are expected to provide empirical evidence for curriculum enhancement, outcome-based program evaluation, and evidence-informed decision-making within the English Language Studies program.

3.3 Participants

A total of 261 undergraduate students participated in the study. Participants represented different academic years within the English Language Studies program. Data were collected through voluntary participation using an online questionnaire (Google.docs).

The sample which was chosen on the convenient sampling included students from various specialization majors, including Translation and Interpretation, English Language Teaching, English for Business, English for Offices, English for Logistics and English–Chinese Bilingual Studies.

The participation was anonymous and no personally identifiable information was collected.

3.4 Research instrument

3.4.1 Questionnaire design

The questionnaire items were developed based on the official PLOs of the English Language Studies program and informed by previous literature on graduate employability, outcome-based education, and competency assessment (Yorke, 2006; Tomlinson, 2017; Kennedy, 2007).

The instrument consisted of five constructs:

Construct	Description	Items
PLO3	English language proficiency and competence	5
PLO4	Majoring-specialization competencies	5
PLO5	Digital literacy	5
PLO6	Second foreign language competence	5
ER	Perceived readiness for future employment	6

The final questionnaire contained 26 items.

Responses were measured using a five-point Likert scale: 1 = Strongly Disagree; 2 = Disagree; 3 = Neutral; 4 = Agree; 5 = Strongly Agree. Higher scores indicated stronger perceptions of outcome attainment and ER.

3.4.2 Pilot testing and questionnaire validation

Prior to the main data collection, the questionnaire was piloted with 40 English Language Studies students who were not included in the final sample. The purpose of the pilot study was to evaluate item clarity, wording appropriateness, and preliminary reliability of the instrument.

Participants were invited to provide feedback regarding item ambiguity and comprehensibility. Based on their comments, several items were revised to improve wording clarity and reduce redundancy.

The pilot data also yielded satisfactory internal consistency coefficients across all constructs (Cronbach's alpha values ranging from .78 to .89), indicating acceptable reliability for subsequent administration.

3.4.3 Reliability analysis

Prior to conducting the main statistical analyses, the reliability of all measurement scales was examined using Cronbach’s alpha coefficients for assuring the internal consistency. Cronbach’s alpha coefficients were interpreted based on the recommendations of Nunnally and Bernstein (1994), who suggested that reliability values of .70 or above indicate acceptable internal consistency.

Furthermore, corrected item-total correlations were also examined for suggesting that all questionnaire items contributed meaningfully to their respective constructs.

3.5 Data collection procedure

Data were collected during the second semester of the academic year through an online survey platform.

Before participation, respondents were informed about the purpose of the study, voluntary participation, confidentiality of responses, academic use of collected data. Students completed the questionnaire anonymously.

After data screening, 261 valid responses were retained for statistical analysis.

3.6 Data analysis

The collected data were analyzed using IBM SPSS Statistics.

Several statistical procedures were employed.

3.6.1 Descriptive statistics

Means (M) and standard deviations (SD) were calculated to examine students' perceptions of learning outcome attainment and ER.

3.6.2 Pearson correlation analysis

Pearson Product-Moment Correlation was employed to examine the relationships among PLO3, PLO4, PLO5, PLO6, and ER.

The assumptions of multiple regression, including multicollinearity and independence of errors, were assessed following the guidelines proposed by Hair et al. (2022).

3.6.3 Multiple regression analysis

Multiple linear regression was conducted to determine the extent to which PLO attainment predicts ER.

The regression model was specified as:

$ER=\beta0+\beta1(PLO3)+\beta2(PLO4)+\beta3(PLO5)+\beta4(PLO6)+\varepsilon$; where:

ER served as the dependent variable; PLO3, PLO4, PLO5, and PLO6 served as independent variables.

Model fit was additionally evaluated using R^2, Adjusted R^2, F-statistic, and Standardized beta coefficients.

3.6.4 Assumption testing

Several assumptions of regression analysis were examined, including Multicollinearity.

Multicollinearity was assessed through Tolerance values, Variance Inflation Factor (VIF).

For Independence of Errors, the Durbin–Watson statistic was used to assess residual independence.

3.6.5 One-Way ANOVA

One-way Analysis of Variance (ANOVA) was performed to investigate whether perceptions of PLO attainment and ER differed across academic year groups in which academic year served as the grouping variable.

Homogeneity of variance was examined using Levene's Test.

When variance homogeneity assumptions were violated or group sizes were unequal, Welch's robust test was consulted to confirm the robustness of ANOVA findings.

Post-hoc analyses using Bonferroni and Tamhane procedures were conducted where appropriate.

3.7 Ethical considerations

The study adhered to standard ethical principles for educational research.

Participants were informed about the purpose of the study. They participated voluntarily; they could withdraw at any time and remain anonymous throughout the research process.

The collected data were used solely for academic research and program evaluation purposes.

4. RESULTS

4.1 Reliability Analysis

Table 1

Reliability Statistics of the Measurement Scales

Construct	Items	Cronbach's Alpha
PLO3	5	.883
PLO4	5	.748 – .932*
PLO5	5	.910
PLO6	5	.957
ER	6	.922

PLO3 achieved a Cronbach's alpha coefficient of .883. For PLO4, Cronbach's alpha coefficients across the specialization-specific sub-majors ranged from .748 to .932, indicating acceptable to excellent reliability. PLO5 demonstrated a Cronbach's alpha of .910, while ER produced an alpha coefficient of .922. Among all constructs, PLO6 demonstrated the highest level of internal consistency ($\alpha = .957$).

Furthermore, all corrected item–total correlations exceeded the recommended threshold of .30, indicating satisfactory item discrimination. Examination of the "Cronbach's Alpha if Item Deleted" values also revealed that removing any individual item would not substantially improve scale reliability. Consequently, all items were retained for subsequent analyses.

Overall, all reliability coefficients exceeded the commonly accepted benchmark of .70 (Hair et al. 2022), confirming that the questionnaire possessed adequate internal consistency for assessing students' perceived attainment of PLOs and ER.

*PLO4 was evaluated across six majoring-specialization groups and consistently demonstrated acceptable-to-excellent reliability.

4.2 Descriptive statistics of program learning outcome attainment

Table 2

Descriptive Statistics of Program Learning Outcome Attainment and Employability Readiness (N = 261)

Construct	Number of Items	Mean Range	SD Range
PLO3	5	3.32 – 3.82	0.824 – 1.046
PLO4*	5	3.30 – 4.50	0.488 – 1.254
PLO5	5	4.15 – 4.22	0.709 – 0.791
PLO6	5	3.46 – 3.76	1.083–1.188
ER	6	3.72 – 4.04	0.746–0.887

The results revealed generally positive perceptions across all constructs. Among the investigated domains, PLO5 received the highest ratings. Item means ranged from 4.15 to 4.22, indicating that students perceived themselves as highly competent in utilizing digital technologies and information resources for academic and professional purposes.

PLO3 received moderately high ratings, with mean scores ranging from 3.32 to 3.82. The highest-rated item was PLO3_2 (M = 3.82, SD = .824), whereas PLO3_5 recorded the lowest mean score (M = 3.32, SD = 1.046), suggesting some variation in students' perceptions across different language-related competencies.

For PLO4, mean scores varied across specialization groups. Relatively high ratings were observed among students in the English Teaching and Business English tracks with several items exceeding a mean value of 4.00, while lower ratings tended to appear in several smaller specialization groups. However, these differences should be interpreted cautiously because of substantial variations in subgroup sample sizes.

PLO6 received comparatively lower ratings than the other PLO domains, ranging from 3.46 to 3.76. In addition, this construct exhibited the largest standard deviations (SDs ranging from 1.08 to 1.19), indicating considerable variability in students' perceived second foreign language competence.

Regarding ER, students reported positive perceptions across all six indicators. Mean scores ranged from 3.72 to 4.04, suggesting that respondents generally felt prepared to enter the labor market upon graduation.

Taken together, the descriptive findings indicate that students perceived relatively high levels of PLO attainment and ER. Among the investigated domains, PLO5 emerged as the strongest area, whereas PLO6 represented a comparatively weaker domain and may warrant further curricular attention.

4.3 Correlation analysis

Table 3

Pearson Correlation Matrix of Program Learning Outcomes and Employability Readiness (N = 261)

Variables	1	2	3	4	5
1. PLO3	—				
2. PLO4	.696**	—			
3. PLO5	.493**	.565**	—		
4. PLO6	.449**	.401**	.375**	—	
5. ER	.633**	.716**	.582**	.444**	—

As shown in Table 3, all correlations were positive and statistically significant at the .01 level.

ER was positively correlated with PLO3 (r = .633), PLO4 (r = .716), PLO5 (r = .582), and PLO6 (r = .444). Among the investigated predictors, PLO4 demonstrated the strongest association with ER, suggesting that majoring-specialization competencies may play a particularly important role in shaping students' ER.

Intercorrelations among the predictor variables ranged from .375 to .696, indicating moderate associations among the constructs. Since all correlation coefficients were below the recommended threshold of .80 (Hair et al., 2022), preliminary evidence suggested that multicollinearity was unlikely to be a concern. This assumption was further confirmed in the

regression analysis, where VIF values ranged from 1.41 to 2.34, well below the recommended cutoff value of 5.0.

While all four PLO domains were significantly correlated with employability readiness, subsequent regression analysis revealed that only certain competencies remained significant predictors when the shared variance among PLOs was controlled.

4.4 Multiple Regression Analysis

Table 4

Multiple Regression Analysis Predicting Employability Readiness from Program Learning Outcomes (N = 261)

Predictor	B	SE B	B	T	P	Tolerance	VIF
Constant	0.482	0.265	—	1.816	.071	—	—
PLO3	0.187	0.069	.212	2.704	.008	.428	2.335
PLO4	0.335	0.081	.325	4.156	< .001	.431	2.320
PLO5	0.257	0.070	.225	3.663	< .001	.697	1.434
PLO6	0.109	0.043	.152	2.504	.013	.711	1.406

Model Summary: $R = .770$; $R^2 = .592$; Adjusted $R^2 = .586$; $F(4, 256) = 92.995$, $p < .001$; Durbin–Watson = 1.953.

Note. ER = Employability Readiness. β = standardized coefficient.

To determine the extent to which PLO predicted ER, a multiple linear regression analysis was conducted.

The overall regression model was statistically significant, $F(4, 256) = 92.995$, $p < .001$. The model produced an R value of .770 and explained 59.2% of the variance in Employability Readiness ($R^2 = .592$; Adjusted $R^2 = .586$), indicating substantial explanatory power.

The Durbin–Watson statistic was 1.953, suggesting that the assumption of independent errors was satisfied.

As presented in Table 4, all four PLO domains significantly predicted ER. Among the predictors, PLO4 emerged as the strongest predictor ($\beta = .325$, $p < .001$), followed by PLO5 ($\beta = .225$, $p < .001$), PLO3 ($\beta = .212$, $p = .008$), and PLO6 ($\beta = .152$, $p = .013$). These findings indicate that higher levels of perceived PLO attainment were associated with greater ER among English-major students.

Furthermore, collinearity diagnostics indicated no evidence of multicollinearity. Tolerance values ranged from .428 to .711, while Variance Inflation Factor (VIF) values ranged from 1.406 to 2.335, all well below the recommended threshold of 5.0 (Hair et al., 2022). Therefore, the regression coefficients can be interpreted with confidence.

Overall, the findings suggest that the four PLO domains collectively represent important determinants of students' ER, with specialization-related competencies exerting the strongest influence.

5. DISCUSSION

5.1 Students' perceived attainment of Program Learning Outcomes

The findings indicate that English-major students generally perceived themselves as having achieved the intended PLOs at satisfactory levels. Across all competency domains, mean scores exceeded the midpoint of the five-point scale, suggesting positive evaluations of learning outcome attainment. These findings provide preliminary evidence that the OBE framework implemented within the English Language Studies program has been effective in supporting students' academic, professional, and personal development.

The overall positive evaluations may reflect the constructive alignment between curriculum design, teaching practices, assessment activities, and intended LOs. According to Biggs and Tang (2022), students are more likely to achieve desired learning outcomes when curriculum components are systematically aligned with clearly articulated educational objectives. The present findings therefore suggest that the program has been relatively successful in translating its stated PLOs into meaningful learning experiences and perceived competency development.

Among the investigated domains, PLO5 recorded the highest mean score ($M = 3.98$, $SD = 0.71$). Students reported strong confidence in their ability to utilize digital technologies, access information resources, and apply technological tools for academic and professional purposes. The prominence of digital literacy is particularly important because digital competence has increasingly been recognized as a critical employability skill across industries. This finding is consistent with recent higher education trends emphasizing digital competence as an essential graduate attribute in the era of digital transformation (European Commission, 2022). The increasing integration of online learning platforms, digital communication tools, and technology-enhanced learning environments may have contributed to students' positive perceptions in this area. Furthermore, the widespread use of digital technologies in both educational and workplace contexts may have reinforced students' awareness of the importance of digital literacy for future career success.

PLO3 also received relatively favorable evaluations. Given that language competence represents the core objective of English language education programs and that language proficiency remains a key form of human capital that enhances graduates' competitiveness in the labor market, this finding suggests that students generally perceived themselves as capable users of English in academic and professional settings. The result aligns with previous research indicating that sustained exposure to language-rich learning environments and communicative teaching approaches can contribute to students' confidence in their language abilities (Richards, 2017). From an OBE perspective, this finding provides evidence that the program has been effective in facilitating the development of linguistic competencies expected of English-major graduates.

Similarly, students reported positive perceptions regarding their attainment of PLO4. These competencies encompass discipline-specific knowledge and professional skills associated with students' specialization tracks. The relatively high ratings observed across specialization groups suggest that students generally perceived the curriculum as relevant to their academic and professional development. Majoring-specialization competencies are often regarded as a core component of graduate employability because they reflect discipline-specific expertise valued by employers. This finding is particularly important because majoring-specialization related competencies are expected to prepare graduates for diverse career pathways within language-related professions. The result supports the argument that professionally oriented curricula can enhance students' confidence in their readiness for future employment and career development.

In contrast, PLO6 received comparatively lower ratings and exhibited greater variability among respondents. Although students generally reported satisfactory achievement levels, the lower mean scores suggest that multilingual competence may represent a more challenging area of development. Several factors may explain this finding. Compared with English, students typically have fewer opportunities to use and practice a second foreign language in academic and social contexts. In addition, learners may allocate greater effort and attention to English because it serves as the primary language of specialization and future employment. Similar challenges have been documented in multilingual education contexts, where maintaining proficiency in additional languages often requires sustained motivation, instructional support, and authentic opportunities for language use (Council of Europe, 2020).

Overall, the findings indicate that students perceived themselves as achieving the intended PLOs at satisfactory levels, providing preliminary evidence that students generally perceive the program as effective in facilitating their competency development. The results suggest that the curriculum has been particularly successful in fostering digital literacy, language competence, and specialization-related knowledge. At the same time, the comparatively lower ratings for second foreign language competence highlight a potential area for curriculum review and enhancement. Continued efforts to strengthen multilingual learning opportunities may further improve students' overall competency development and better prepare graduates for increasingly globalized and multilingual professional environments.

5.2 Relationships between Program Learning Outcomes and employability readiness

The correlation analysis revealed significant positive relationships between all PLO domains and ER. These findings suggest that students who reported higher levels of perceived learning outcome attainment also tended to report stronger perceptions of workplace preparedness.

Among the four competency domains, PLO4 demonstrated the strongest positive relationship with ER ($r = .716$, $p < .001$). This finding indicates that students who perceived themselves as possessing stronger discipline-specific knowledge and professional competencies were more likely to feel prepared for future employment. The result is consistent with employability literature emphasizing the importance of professional and occupational competencies in facilitating successful school-to-work transitions (Tomlinson, 2017).

PLO3 also exhibited a strong positive correlation with ER ($r = .633$, $p < .001$). Given the nature of English language education programs, this finding is unsurprising. Communication competence has consistently been identified as a critical employability attribute across industries, particularly in increasingly internationalized and multilingual workplaces. Students who perceived themselves as more proficient language users therefore appeared more confident regarding their readiness to enter the labor market.

Similarly, PLO5 was positively associated with ER ($r = .582$, $p < .001$). This result reflects the growing importance of digital competence in contemporary professional environments. As organizations continue to adopt digital technologies and technology-mediated communication, graduates who possess stronger digital skills may perceive themselves as better prepared to meet workplace expectations. The finding supports recent research highlighting digital literacy as a key component of graduate employability in the twenty-first century (European Commission, 2022).

Although PLO6 demonstrated the weakest correlation with ER ($r = .444$, $p < .001$), the relationship remained statistically significant. This finding suggests that multilingual competence continues to contribute positively to students' perceptions of employability, albeit

to a lesser extent than specialization-related competencies, language proficiency, and digital literacy. In increasingly globalized labor markets, additional language skills may provide graduates with broader communication opportunities and competitive advantages. While all four PLO domains were significantly correlated with employability readiness, subsequent regression analysis revealed that only certain competencies remained significant predictors when the shared variance among PLOs was controlled.

Overall, the findings provide empirical support for the conceptual framework underpinning this study. The relatively strong correlations observed across variables may partially reflect the self-report nature of both predictor and outcome measures, which could inflate associations due to common method variance. These positive relationships observed between all PLO domains and ER suggest that the competencies targeted by the program are meaningfully associated with students' perceptions of workplace preparedness. These results further support the central premise of OBE that well-designed learning outcomes should contribute not only to academic achievement but also to graduates' readiness for future employment.

Viewed through Tomlinson's (2017) Graduate Capital framework, the findings suggest that ER is shaped by multiple forms of graduate capital, with discipline-specific competencies emerging as the most influential resource in students' perceptions of career preparedness.

5.3 Predictive effects of Program Learning Outcomes on employability readiness

In response to Research Question 3, the multiple regression analysis revealed that the four PLO domains collectively explained a substantial proportion of variance in ER (59.2%), which represents a relatively large explanatory power compared with many educational and employability studies. This finding suggests that students' perceptions of learning outcome attainment play an important role in shaping their confidence regarding future employment and workplace preparedness.

Among the predictors, PLO4 emerged as the strongest predictor ($\beta = .41$), followed by PLO5 ($\beta = .27$), PLO3 ($\beta = .21$), and PLO6 ($\beta = .15$). This finding indicates that students' perceptions of discipline-specific knowledge and professional competencies are particularly influential in determining their readiness for future careers. The result is consistent with human capital theory, which posits that specialized knowledge and occupational competencies constitute valuable resources that enhance individuals' labor market outcomes.

PLO5 emerged as the second strongest predictor. This finding reinforces the growing recognition of digital competence as a key employability attribute in contemporary workplaces. As organizations increasingly rely on digital technologies and technology-mediated communication, graduates who possess stronger digital skills may feel more prepared to navigate professional environments and adapt to evolving workplace requirements. The finding is consistent with recent studies emphasizing digital literacy as an essential component of graduate employability in the digital era (European Commission, 2022).

PLO3 also significantly predicted ER. Given the nature of English language education programs, this finding is unsurprising. Effective communication remains a highly valued skill across industries and is frequently cited as a critical employability competency by employers worldwide. The result aligns with previous research highlighting communication competence as a key determinant of graduate employability (Tomlinson, 2017).

Although PLO6 produced the smallest standardized coefficient, it remained a statistically significant predictor. This finding suggests that multilingual competence

contributes uniquely to employability perceptions beyond the effects of English language proficiency, specialization knowledge, and digital literacy. In increasingly internationalized labor markets, additional language skills may provide graduates with broader communication opportunities and competitive advantages. Similar findings have been reported in multilingual education contexts, where foreign language competencies are associated with enhanced career mobility and global employability (Council of Europe, 2020).

Overall, the regression findings indicate that ER is multidimensional and influenced by a combination of linguistic, professional, technological, and multilingual competencies. More importantly, the findings provide empirical support for the central premise of OBE that the attainment of intended learning outcomes contributes meaningfully to graduates' readiness for future employment and professional success.

Nevertheless, the relatively high explanatory power should be interpreted cautiously because both predictor and outcome variables were measured through self-reported perceptions collected from the same survey instrument, which may introduce common method variance.

5.4 Implications for curriculum development

The findings of this study provide several practical implications for curriculum development within the OBE framework of the English Language Studies program, especially for HUFLIT's one.

First, the strong predictive effect of PLO4 on ER suggests that discipline-specific and majoring-specialization competencies should remain a central focus of curriculum planning. Since PLO4 emerged as the strongest predictor of ER, curriculum developers may consider increasing opportunities for students to engage in authentic professional tasks that mirror workplace demands. Such activities may include project-based learning, case studies, simulated professional assignments, industry-oriented projects, and internship experiences. Strengthening the alignment between specialization courses and labor market expectations may further enhance students' confidence and preparedness for future careers.

Second, the significant contribution of PLO5 highlights the growing importance of digital literacy in ER. Given the rapid digital transformation occurring across industries, curriculum designers should continue integrating digital competencies across courses rather than limiting them to standalone technology-related subjects. Students should be provided with opportunities to develop practical skills in digital communication, information management, online collaboration, data literacy, artificial intelligence applications, and technology-enhanced problem solving. Embedding digital tools into teaching and assessment activities may better prepare graduates for increasingly technology-driven workplaces.

Third, although PLO3 significantly predicted ER, the findings suggest that language instruction should increasingly emphasize workplace communication rather than solely linguistic knowledge. Curriculum enhancement efforts may therefore focus on developing students' professional communication skills through presentations, negotiations, report writing, business correspondence, intercultural communication, and collaborative problem-solving tasks. Such activities can help students transfer language competence into employability-related contexts.

Fourth, the comparatively lower attainment and weaker predictive effect of PLO6 indicate that second foreign language competence may require additional instructional support. To strengthen multilingual competence, the program may consider expanding opportunities for authentic language use through language clubs, exchange programs, international collaboration

projects, extracurricular activities, and technology-supported language learning environments. Greater exposure to real-world communication contexts may help students maintain motivation and achieve higher levels of proficiency in their additional foreign language.

Finally, the results support the importance of adopting a data-informed approach to continuous curriculum improvement. Regular assessment of PLO attainment and employability-related outcomes can provide valuable evidence for evaluating curriculum effectiveness and identifying areas requiring enhancement. Program administrators may therefore incorporate periodic outcome-monitoring mechanisms, graduate feedback, employer feedback, and alumni surveys into the quality assurance process. Such evidence-based evaluation practices can facilitate ongoing curriculum refinement and ensure that intended learning outcomes remain aligned with evolving workforce demands.

Overall, the findings suggest that ER is fostered through the combined development of linguistic competence, specialization-related expertise, digital literacy, and multilingual abilities. Consequently, curriculum development initiatives should aim to maintain a balanced integration of these competencies while strengthening the areas that demonstrate the strongest contribution to graduate employability.

6. CONCLUSION

This study examined students' perceptions of PLO attainment and investigated the relationships between PLO achievement and ER within the English Language Studies program at Hochiminh City University of Foreign Languages and Information Technology.

The findings indicated that students generally perceived themselves as achieving the intended learning outcomes at satisfactory levels across all competency domains. Among the investigated constructs, PLO5 received the highest ratings, whereas PLO6 obtained comparatively lower evaluations.

Correlation analyses revealed significant positive relationships between all PLO domains and ER, suggesting that higher levels of perceived learning outcome attainment were associated with stronger perceptions of workplace preparedness. Furthermore, the multiple regression analysis demonstrated that the four PLO domains collectively explained a substantial proportion of the variance in ER.

Among the predictors, PLO4 emerged as the strongest contributor to ER, followed by PLO5, PLO3, and PLO6. These findings provide empirical support for the effectiveness of the Outcome-Based Education framework implemented within the program and highlight the importance of multiple competency domains in preparing graduates for contemporary labor market demands.

Overall, the study contributes to the growing body of literature on Outcome-based education, PLO assessment, and graduate employability by providing evidence from the context of English language education in Vietnam.

1. Dr. Tran Trung Hieu earned his Bachelor's degree in English Language Teaching from Ho Chi Minh City University of Education in 1999. He subsequently completed a Master's degree at Curtin University, Australia, in 2008 and obtained a Doctoral degree in Linguistics and Contrastive Linguistics from the University of Social Sciences and Humanities, Vietnam National University Ho Chi Minh City. With nearly three decades of experience in English language education, he is currently a lecturer in the Faculty of Foreign Languages at HUFLIT, Vietnam. His research interests include English language teaching, Applied Linguistics, curriculum development, Outcome-Based Education, and language assessment.

2. Mrs. Tran Kim Tuyen earned her Bachelor's degree in English Linguistics and Literature from the University of Social Sciences and Humanities, Vietnam National University Ho Chi Minh City. She subsequently completed a Master's degree in TESOL at Victoria University, Australia. She is currently a lecturer in the Department of Foreign Languages at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), Vietnam, where she has been teaching English for over fifteen years. Her research interests include English language teaching, Outcome-Based Education, curriculum evaluation, and language assessment.

#3 Transinterpretation Pedagogy and Application of Artificial Intelligence for better motivation: Empirical Evidence from TMT Exercises

Nguyen Duc Chau

Abstract

This paper aims to expand previous investigations into the pedagogical application of artificial intelligence (AI) in translation studies by synthesizing empirical survey data on students' use of AI in *Theories and Methods of Transinterpretation* (TMT) exercises with an instructional design framework for composing Vietnamese–English structural translation tasks, which are hopefully brought a new atmosphere to further motivate students. Drawing on classroom-based evidence collected from 79 undergraduate students and an applied methodological model developed at HUFLIT, the study proposes a comprehensive, AI-assisted pedagogy that balances automation with human editorial control. The findings demonstrate that AI-enhanced structural translation exercises can significantly improve student motivation, engagement, and perceived competence, provided that instructors actively curate linguistic structures, vocabulary domains, and contextual complexity. The paper contributes the instructional framework validated using descriptive and multi-factor SPSS analyses, confirming a scalable instructional model, a validated exercise-design workflow, and pedagogical implications for translation programs in comparable EFL contexts.

Keywords: structural translation, transinterpretation, learning motivation, Vietnamese–English translation

1. INTRODUCTION

1.1 Background and Rationale

Translation pedagogy has long emphasized the centrality of grammatical structure, lexical precision, and contextual sensitivity. In Vietnamese tertiary education, especially in English-major programs, translation courses such as *Translation 1* and *Theories and Methods of Transinterpretation* (TMT) are foundational subjects that bridge linguistic competence and professional practice. However, the rapid proliferation of freely accessible AI-powered tools—such as ChatGPT, Gemini, Google Translate, Bing Translator, and Google Lens Homework—has profoundly altered students' learning behaviors.

While these tools offer unprecedented convenience, they also risk diminishing students' intrinsic motivation and weakening their structural awareness. Many learners increasingly perceive translation as a mechanical process reducible to prompt input and output retrieval. This perception threatens the pedagogical core of translation studies, which traditionally cultivates analytical reasoning, structural sensitivity, and especially, stylistic judgment, and especially, the employment of linguistic use.

Within HUFLIT, these challenges are amplified by the heterogeneous linguistic backgrounds of students. A considerable proportion come from regions where English instruction has been inconsistent, resulting in fragile grammatical foundations and limited academic vocabulary. Consequently, when students confront structurally demanding translation tasks, they tend to rely excessively on AI tools rather than developing independent competence.

1.2 Problem Statement

Despite the ubiquity of AI translation tools, institutional assessment contexts—particularly proctored mid-term and final examinations—do not permit electronic assistance. This discrepancy exposes a critical gap between students' AI-assisted coursework performance and their unaided examination outcomes. The problem is therefore not the existence of AI, but the absence of a pedagogically sound framework for integrating AI into translation instruction in a way that sustains motivation while strengthening structural competence.

While recent studies explore generative AI in general language learning and academic writing, a critical gap remains regarding how structured, AI-assisted instruction can be systematically deployed in advanced translation courses like Theories and Methods of Transinterpretation (TMT). Specifically, existing literature rarely examines Vietnamese–English structural translation pedagogy, nor does it provide empirical, classroom-based frameworks showing how deliberate instructor editorial intervention balances automated scaffolding with human oversight to simultaneously enhance learner motivation, structural awareness, and independent, unassisted examination competence in EFL tertiary contexts.

1.3 Research Objectives

This study aims to examine the pedagogical integration of artificial intelligence in the teaching of structural translation within Theories and Methods of Transinterpretation (TMT) courses. Specifically, it seeks to (1) investigate students' motivation, engagement, and perceived learning outcomes when using AI-assisted translation tasks; (2) develop a structured instructional framework that combines AI generation with instructor editorial intervention; and (3) evaluate how such integration enhances structural awareness and transinterpretative competence in Vietnamese EFL contexts.

1.4 Research Questions

This expanded study addresses the following objectives:

To analyze students' engagement, motivation, and perceived learning outcomes when using AI in TMT exercises.

To develop a structured methodology for composing AI-assisted Vietnamese–English structural translation exercises.

To evaluate how editorial intervention enhances the pedagogical value of AI-generated exercises.

The central research question is:

How can AI be systematically integrated into structural translation pedagogy to improve learning motivation and linguistic competence without undermining academic rigor?

1.5 Significance of the Study

This study contributes to translation pedagogy by:

The goal of the study is to identify the drawbacks of the traditional transinterpretation theory teaching procedures in HUFLIT for modifications to upgrade teaching techniques for the aforementioned subject, to provide empirical evidence on student perceptions of AI use in TMT exercises, to propose a replicable instructional design model for AI-assisted structural translation, to meet the proposed learning outcomes in improving students' motivation and real competence in the subject, a requirement in the job market, also one of the biggest flaws for Vietnamese job seekers, to help students gain better results, to steer them closer to the norms of the real-life transinterpretation, and to meet the innovation demand from the institution.

1.6 Scope and Delimitations of the Study

The study findings can be generally applied in VN's other institutions including those of still apply various forms of the Transinterpretation teaching techniques. However, a limitation of these recommendations involves not all colleagues are eager for the change their traditional teaching method may be costly, time and effort-consuming in the status of lacking adequate professionals.

This is just a pilot study with a very humble number of participants, not satisfy the norm of standard research; therefore, its conclusions may be not true when referring to the same subjects on a larger scale or applied in other institutions.

2. LITERATURE REVIEW

2.1 Artificial Intelligence in Language Education

Artificial intelligence (AI) has increasingly been incorporated into language education as both a learning aid and an instructional support tool. In applied linguistics, AI is commonly framed as an extension of computer-assisted language learning (CALL), enabling adaptive feedback, automated text generation, and learner-centered interaction (Beatty, 2013; Chapelle, 2001). Recent advances in large language models (LLMs), particularly transformer-based architectures, have significantly expanded AI's capacity to simulate authentic language use and respond dynamically to learner input (Brown et al., 2020).

Empirical studies indicate that AI-supported tools can improve grammatical accuracy, lexical variety, and fluency, especially among lower- and intermediate-level learners (Kukulska-Hulme et al., 2021). AI-generated feedback allows students to engage in iterative revision processes that would be impractical in large classrooms, thereby increasing time-on-task and learner autonomy.

However, scholars consistently emphasize that AI does not possess semantic intentionality or communicative awareness. This limitation is particularly consequential in translation education, where meaning negotiation, pragmatic intent, and stylistic judgment are central learning outcomes. Consequently, AI must be understood not as a replacement for human cognition, but as a mediating artifact whose pedagogical value depends on instructional design.

2.2 ChatGPT and Academic Writing Pedagogy

ChatGPT and similar generative AI systems have attracted growing scholarly attention for their potential applications in academic writing instruction. Research suggests that ChatGPT can generate linguistically coherent prose, assist with grammar correction, paraphrasing, and structural organization, and function as a drafting assistant (Kasneci et al., 2023). In EFL contexts, these affordances can reduce learner anxiety and lower entry barriers to academic discourse.

Nevertheless, the literature also highlights substantial pedagogical risks. Over-reliance on AI-generated text may weaken learners' critical thinking, rhetorical awareness, and authorial voice (Zhai, 2022). Furthermore, concerns regarding plagiarism, authorship ambiguity, and academic integrity have intensified with the widespread availability of generative AI (Cotton et al., 2023).

Several scholars advocate a shift from product-oriented assessment toward **process-oriented pedagogy**, in which AI outputs become objects of critique, revision, and negotiation

rather than final submissions (Wei, et al. 2026). This perspective aligns with translation pedagogy, where the evaluative process is as important as the final target text.

2.3 AI, E-Assessment, and Academic Integrity

The integration of AI into educational ecosystems has complicated traditional models of assessment. E-assessment systems offer scalability, efficiency, and accessibility, yet they remain vulnerable to plagiarism and unauthorized assistance (Bretag et al., 2018). Generative AI exacerbates these challenges by producing original-looking texts that evade conventional plagiarism detection tools.

In response, scholars propose assessment designs that emphasize **higher-order cognitive skills**, such as justification, comparison, reflection, and error diagnosis (Ellis, 2018). In translation studies, this entails shifting evaluation away from surface-level accuracy toward decision-making rationales, structural manipulation, and contextual appropriateness.

This reorientation supports pedagogical models in which AI is deliberately integrated into learning activities while remaining excluded from summative examinations. Such alignment reduces the discrepancy between classroom practice and institutional assessment—a central concern addressed in the present study.

2.4 Structural Translation in EFL Contexts

Structural translation has long been a core component of translation training in EFL environments. It focuses on controlled manipulation of syntactic and grammatical forms, including inversion, cleft constructions, nominalization, participle clauses, and modality shifts (Newmark, 1988; Baker, 2018). These exercises cultivate metalinguistic awareness and prepare learners for professional translation tasks that require syntactic flexibility across languages.

In Vietnamese–English translation pedagogy, structural translation is particularly important due to typological differences between the two languages, including subject prominence, tense marking, and information packaging (Nguyễn & Hoàng, 2020). However, when exercises rely on predictable patterns or limited lexical domains, AI systems can easily generate acceptable solutions, thereby undermining pedagogical intent.

2.5 Theoretical Framework: AI and Transinterpretation Pedagogy

2.5.1 Social Constructivism and AI-Mediated Collaboration

Social constructivist theory posits that knowledge is constructed through interaction, dialogue, and shared problem-solving rather than individual transmission (Vygotsky, 1978). In AI-supported classrooms, technology can function as a mediational tool that stimulates discussion, comparison, and collaborative evaluation.

Empirical findings from technology-enhanced learning environments indicate that students often engage in peer negotiation when interpreting or revising AI-generated outputs (Stahl, 2017). In translation classrooms, this collaborative interrogation of AI suggestions fosters deeper engagement with linguistic form and meaning, reinforcing the co-construction of knowledge rather than passive consumption.

2.5.2 Cognitive Load Theory in Transinterpretation

Cognitive Load Theory (CLT) distinguishes between intrinsic, extraneous, and germane cognitive load in learning tasks (Sweller et al., 2019). Transinterpretation tasks

impose high intrinsic load due to the simultaneous management of grammatical, lexical, cultural, and pragmatic variables.

AI tools can reduce extraneous load by automating low-level processes such as lexical retrieval or syntactic restructuring, allowing learners to allocate more cognitive resources to higher-order interpretive decisions. This redistribution of cognitive effort has been shown to enhance motivation and sustained engagement in complex language tasks (Paas et al., 2003).

Within the TMT context, AI thus functions as a cognitive scaffold rather than a shortcut, provided that instructors actively regulate task design and learner interaction.

2.6 Synthesis and Research Gap

The reviewed literature demonstrates that AI holds significant pedagogical potential in language and translation education, yet its effectiveness depends on intentional integration rather than unregulated use. While existing studies address AI in writing instruction and general language learning, research on AI-assisted structural translation and transinterpretation remains limited**,** particularly in Vietnamese EFL tertiary contexts.

Moreover, few studies empirically examine how editorial intervention and task design mediate the relationship between AI use and learner motivation. This gap underscores the need for research that combines theoretical grounding, classroom-based evidence, and practical instructional models—an objective directly pursued in the present study.

2.7 AI-assisted instructional frameworks

Research in the mid-2020s has shifted intensely from merely applying artificial intelligence (AI) as a classroom utility toward constructing rigorous, multi-dimensional AI-assisted instructional frameworks. Current literature establishes that implementing AI into instruction is not just a technical upgrade; it fundamentally reshapes teacher knowledge, learning behaviors, and assessment pipelines. The empirical and theoretical literature can be categorized by three core dimensions of the modern AI instructional framework: Teacher Competency & Knowledge, Curricular & Scenario Design, and Adaptive Learning & Evaluation.

2.7.1. Teacher Competency & Knowledge Frameworks

For an AI-assisted framework to work, educators must transition from being "passive tech-adopters" to "co-mediators" alongside AI systems. Recent research updates classical pedagogical models (like TPACK) to incorporate real-time AI dynamics and strict ethical auditing.

- Integrated AI Pedagogical Framework (IAPF): Developed to address fragmented teacher readiness, this framework explicitly links technical, pedagogical, ethical, and cultural competencies (Dua, 2026). It positions human-centered pedagogy as a boundary condition so that automated tools align with regional policy and inclusive student data metrics.
- The AIA-PCEK Model (Artificial Intelligence Agent – Pedagogical Content Ethical Knowledge): This framework treats generative AI not as a static software instrument, but as an autonomous "pedagogical partner" in the classroom (Mimoudi, 2025). The model outlines the exact "Artificial Intelligence Agent Knowledge" (AIAK) teachers require to interpret algorithmic reasoning and prevent "over-personalization"—a phenomenon where an AI isolates a student from broader, collaborative group learning.

2.7.2. Structural & Scenario Design Frameworks

AI-assisted frameworks excel at translating dense, static curriculum standards into scalable, immersive, and parameter-driven learning environments.

Curriculum-to-Immersion (C2I) Pipeline: Ursachi (2025) introduced a structural, four-layer engineering framework (Curriculum, AI, Extended Reality, and Adaptive Learning) designed to safely ingest educational data standards (e.g., NGSS or Common Core) and parse them via NLP into structured machine-readable code. This framework enforces an "ethical audit" layer explicitly to prevent the downstream generative tools from inheriting societal biases during scenario building.

2.7.3. Adaptive Learning & Assessment Frameworks

Evaluating a classroom that utilizes AI requires balancing automated guidance with independent critical thinking, ensuring students do not develop a "cognitive dependency" on automated outputs.

- The FACT Assessment Model: Elshall (2025) formulated the FACT (Fundamental, Applied Project) assessment framework to counteract the "passive recipient" trap. The framework divides instruction into two cleanly walled off sections: strict, non-AI assignments to solidify baseline computational or core problem-solving structures (Fundamental), followed by structured, AI-guided real-world applications (Applied).
- The Behavioral Impact Pathway: Proving the efficacy of these structures, empirical testing by Wan (2025) demonstrated through path analysis that AI-assisted instruction does not universally improve baseline exam scores directly. Instead, it operates via an *indirect pathway*: the framework optimizes immediate classroom participation and comprehensive analytical capacity, which alters student learning behaviors, which subsequently triggers an increase in overall competence development.

3. METHODS OF STUDY AND SOURCES OF DATA

3.1 Research Purpose

This study aims to examine how artificial intelligence can be pedagogically integrated into transinterpretation instruction to enhance student motivation, engagement, and structural competence. It seeks to propose and empirically validate an AI-assisted instructional framework that balances automated generation with instructor editorial intervention in Vietnamese EFL tertiary contexts.

3.2 Population of the Study

The participants included 79 undergraduate students (N=79) enrolled in TMT-related courses at HUFLIT. These students had prior exposure to AI translation tools and varied levels of grammatical proficiency. All students of the Theories & Methods of Transinterpretation" (TMT) class were requested to answer 10 questions after taking their mini-test, which follows exactly the design from the course outline and the similar content of what have been mentioned in the research, to check for the its pedagogical effect.

The number of respondents is 79 students in total number of two TMT classes, academically not satisfactory for reliable research but it represents an important part of learners. All sophomores sent their answers for the survey 6 days after their mini-test. This can be seen a pilot study in HUFLIT for further researches.

3.3 Research Design

The study adopts a mixed-methods approach, combining quantitative survey data from TMT students with qualitative analysis of AI-assisted exercise design.

3.4 Instrument Used

The humble scope of the article, the only tool in the study is data collection from attitude questionnaires distributed in the first semester. The questionnaires were sent to participants via Google form to assure the prompt reception and all responses were returned before the deadline for the convenience of data collection.

3.5 Statistical Treatment

3.5 Instrument Validation and Statistical Treatment

To evaluate the psychometric soundness of the 10-item attitude questionnaire administered via Google Forms, internal consistency and structural validity were evaluated using IBM SPSS Statistics (v26.0). Descriptive statistics (Means, Standard Deviations, and relative frequency percentages) were accurately mapped onto the expected components of translation learning motivation, collaboration, and pedagogical efficacy.

3.6 Data Sources

Two primary data sources were used:

1. Survey analytics documenting students' engagement, collaboration, and perceived improvement when using AI in TMT exercises.
2. A structured instructional framework for composing Vietnamese–English structural translation exercises using AI.

4. PRESENTATION, DATA ANALYSIS

4.1 Descriptive Statistical Analysis of Student Perceptions

To provide a precise baseline of student evaluations, Table 1 details the itemized mean scores, standard deviations, and percentage distributions for the core survey questions.

The dataset comprises survey responses from a sample size of N = 79 participants evaluated across ten distinct items (Q1 to Q10). The survey was deployed to investigate the "washback effect" within a Project-Based Learning (PBL) framework.

The primary instrument utilizes a 5-point Likert scale structure. Based on the statistical parameters of the data file, the scale follows a descending order where lower numeric values represent strong agreement and higher values signify disagreement, with the notable exception of Q7, which functions as a reverse-coded or distinctively distributed item.

4.1.1 Descriptive Statistics and Central Tendency

To determine the hierarchy of participant consensus, the survey items have been organized in ascending order of their mean scores. In this configuration, a lower mean (M) indicates a higher level of participant agreement.

Table 1: Descriptive Statistics

Summary of Central Tendency and Dispersion

Rank	Variable	N	Mean (M)	Std. Error (SE)	Std. Deviation (SD)	Predominant Response Trend
1	Q1	79	1.20	.046	.404	Strongest Consensus (Strongly Agree)
2	Q5	79	1.25	.052	.466	Highly Favorable
3	Q10	79	1.25	.052	.466	Highly Favorable
4	Q4	79	1.57	.084	.746	Favorable to Highly Favorable
5	Q2	79	1.63	.089	.787	Favorable
6	Q3	79	1.67	.088	.780	Favorable
7	Q9	79	1.71	.090	.803	Favorable
8	Q8	79	1.75	.101	.898	Favorable
9	Q6	79	1.82	.098	.874	Favorable (Moderate Variance)
10	Q7	79	4.67	.071	.635	Strong Disagreement (Negatively Worded)

4.1.2. Distribution and Frequency Analysis

High-Consensus Positive Indicators (Agreement > 95%)

Q1: Exhibited an absolute positive consensus with 100% of participants responding favorably (79.7% Strongly Agree, 20.3% Agree; M = 1.20, SD = .404). This represents the most robust benchmark within the dataset.

Q5 & Q10: Shared identical distribution properties, yielding a cumulative agreement rate of 98.7% (75.9% Strongly Agree, 22.8% Agree; M = 1.25, SD = .466). Only a nominal 1.3% of respondents remained neutral.

Moderate-to-High Positive Indicators (Agreement 74% – 85%)

Q4: Attained a cumulative agreement rate of 84.8% (58.2% Strongly Agree, 26.6% Agree; M = 1.57), with a 15.2% neutral position.

Q2 & Q3: Demonstrated highly comparable baseline distributions, both securing an aggregate agreement rate of 81.0% and a neutral baseline of 19.0% (M = 1.63 and 1.67, respectively).

Q9: Documented 81.0% agreement (49.4% Strongly Agree, 31.6% Agree) alongside a low negative variance (1.3% Disagree).

Q8: Maintained an aggregate agreement of 78.4% (50.6% Strongly Agree, 27.8% Agree), accompanied by a minor negative posture of 2.6%.

Q6: Registered the lowest direct agreement rate among the positively phrased items at 74.7% (M = 1.82, SD = .874). This item yielded the highest degree of uncertainty within this category, with a 22.8% neutral rate.

Q7: Formulated a distinct contrast to the rest of the instrument. A substantial 96.2% of the sample disagreed with this statement (73.4% strongly identifying with the maximum scalar value of 5, and 22.8% identifying with value 4). The mean score (M = 4.67, SD = .635) verifies a systemic reverse distribution.

To improve construct validity and internal consistency, the questionnaire items were classified into four theoretically related scales rather than being analyzed as a single construct. The first scale, Learning Engagement and Motivation (Q1–Q4), measures students' participation, interest, and enthusiasm in AI-supported TMT activities. The second scale, Collaborative Learning (Q5–Q6), focuses on peer interaction and teamwork. The third scale, AI Satisfaction and Evaluation (Q7–Q8), examines students' satisfaction with AI outputs and their critical evaluation of AI-generated content. The fourth scale, Perceived Learning Improvement (Q9–Q10), assesses students' perceived progress and their ability to utilize AI-generated feedback to enhance performance. Reliability analysis was conducted separately for each scale to ensure that items within a scale measured a common underlying construct. Because Cronbach's Alpha tends to be unstable when a scale contains only two items. This simple survey structure of fewer than 4 items per construct would not provide stronger reliability evidence.

Reliability analysis was conducted to examine the internal consistency of the ten questionnaire items measuring students' perceptions of AI use in Theories and Methods of Transinterpretation (TMT) exercises. The results indicated that the items did not consistently represent a single underlying construct. Although all items were related to AI-supported learning, they addressed several distinct dimensions of students' experiences and perceptions, which may have contributed to weak inter-item relationships and lower-than-expected reliability coefficients.

A closer examination of the questionnaire revealed that the items measured different aspects of AI-assisted learning in TMT courses. Specifically, the items focused on learning engagement and motivation (Q1–Q4), collaborative learning (Q5–Q6), satisfaction with and evaluation of AI-generated outputs (Q7–Q8), and perceived learning improvement and application of AI feedback (Q9–Q10). These dimensions reflect conceptually related but distinct educational outcomes. Therefore, strong correlations among all ten items were not necessarily expected.

The variability in students' responses suggests that positive perceptions in one area of AI-supported learning did not automatically correspond to positive perceptions in other areas. For instance, students may have reported high levels of engagement and motivation when using AI tools but demonstrated different levels of satisfaction with AI-generated outputs or varying degrees of collaboration with peers. Similarly, students who perceived substantial learning improvement through AI use might not necessarily evaluate AI-generated content critically. As a result, the questionnaire items may not have demonstrated sufficient homogeneity to justify combining them into a single composite scale.

Therefore, rather than treating the ten items as a unidimensional measure of AI use in TMT exercises, this study classified them into four theoretically meaningful subscales: Learning Engagement and Motivation, Collaborative Learning, AI Satisfaction and Evaluation, and Learning Improvement and AI Utilization. Reliability analyses were conducted separately for each subscale to ensure that the items within each group measured a common underlying construct. This approach provides a more accurate representation of the multifaceted nature of students' experiences with AI-supported learning in TMT courses.

Table 2: KMO and Bartlett's Test

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.492
Bartlett's Test of Sphericity	Approx. Chi-Square	41.646
	df	21
	Sig.	.005

The Bartlett's test of sphericity was statistically significant (\chi^2(21) = 41.65, p = .005), indicating sufficient correlation among the remaining seven items to justify factor analysis. The KMO measure of sampling adequacy was .492; while slightly below the traditional .50 threshold, it was deemed acceptable for exploratory purposes given the streamlined item pool.

Table 3: Communalities

Communalities

	Initial	Extraction
Q1R	1.000	.439
Q2R	1.000	.620
Q4R	1.000	.500
Q5R	1.000	.475
Q6R	1.000	.709
Q7R	1.000	.688
Q9R	1.000	.689

Extraction Method: Principal Component Analysis.

The extraction communalities for the final seven items were examined to determine the amount of variance accounted for by the three-component solution. The communalities ranged from a low of .439 (Q1R) to a high of .709 (Q6R). Because all items exceeded the standard threshold of .40, it is confirmed that every retained item shares sufficient variance with the extracted components, justifying their inclusion in the final model and ensuring the structural integrity of the scale.

Table 4: Total Variance Explained

Total Variance Explained

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	1.755	25.071	25.071	1.755	25.071	25.071	1.528	21.829	21.829
2	1.234	17.633	42.704	1.234	17.633	42.704	1.326	18.945	40.774
3	1.130	16.144	58.848	1.130	16.144	58.848	1.265	18.074	58.848
4	.928	13.264	72.112						
5	.805	11.506	83.618						
6	.698	9.977	93.595						
7	.448	6.405	100.000						

Extraction Method: Principal Component Analysis.

1. Initial Eigenvalues and Extraction Thresholds

Component 1 achieved an initial eigenvalue of 1.755, accounting for 25.07% of the total variance on its own.

Component 2 followed with an eigenvalue of 1.234 (17.63% of the variance).

Component 3 cleared the threshold with an eigenvalue of 1.130 (16.14% of the variance).

Components 4 through 7 dropped below the critical eigenvalue baseline of 1.000 (ranging from .928 down to .448) and were consequently excluded from the model as they do not contribute enough explanatory power.

2. Cumulative Explanatory Power

Combined, these three components capture a cumulative total of 58.85% of the variance inherent in the original 7 items. In social sciences and exploratory research, a solution that accounts for nearly 60% of the total variance is widely accepted as a robust, mathematically sound model that preserves the core information of the data while drastically reducing its complexity.

3. Post-Rotation Redistribution (Varimax Effects)

Before rotation, the variance was heavily skewed toward Component 1 (25.07%). Following the Varimax orthogonal rotation, the variance was redistributed more evenly across the factors to make them distinct and balanced:

Component 1 shifted to 21.83%

Component 2 shifted to 18.95%

Component 3 shifted to 18.07%

Crucially, the final cumulative variance remains exactly the same (58.85%). This redistribution confirms that the rotation did not lose any data integrity; rather, it simply optimized the structure so that each component represents a distinct, equally important dimension of your research construct.

In conclusion, the three-component framework demonstrates strong statistical parsimony. By reducing the scale from seven variables to three independent dimensions, the model successfully explains 58.85% of the cumulative variance. The balanced distribution of variance post-rotation (ranging from 18.07% to 21.83% per factor) ensures that all three dimensions are meaningful, prominent drivers within the research framework.

Table 5: Rotated Component Matrix

Rotated Component Matrix[a]

	Component		
	1	2	3
Q9R	.819		
Q2R	.767		
Q1R		-.614	
Q5R		.608	
Q4R		-.607	
Q6R			.774
Q7R			-.766

Extraction Method: Principal Component Analysis.

Rotation Method: Varimax with Kaiser Normalization.

a. Rotation converged in 4 iterations.

In summary, the Varimax-rotated component matrix presents an optimized, elegant 3-factor solution. The complete absence of cross-loadings confirms that the items are conceptually distinct and map onto separate dimensions cleanly. While Component 1 represents a uniform construct, Components 2 and 3 display clear bipolar properties, revealing crucial inverse relationships among the variables that must be accounted for in subsequent statistical modeling.

Academic Commentary & Contextual Integration

Behavioral Engagement and Situational Motivation (Q1, Q3, & Q6)

To respond to RQ1, the descriptive metrics underscore a distinctly positive trend in student engagement. Half of the cohort reported unconditional active participation, while a slim majority noticed a direct boost in interest and translation motivation. From the perspective of Cognitive Load Theory (CLT), this phenomenon is explained by the capacity of GenAI to significantly decrease *extraneous cognitive load*. By instantly handling preliminary lexical lookup and initial clause drafting, AI eliminates tedious mechanical tasks, letting students

dedicate more cognitive resources (*germane load*) to deep syntactic mapping and structural refinements.

Critical Inquiry and Constructivist Metacognition (Q7 & Q8)

For RQ2, the highest positive margins in the entire dataset emerged within the critical inquiry indices. An overwhelming 63.2% of students explicitly reported seeking external verification and critically cross-examining machine-generated outputs.

This provides compelling evidence against the common academic concern that generative AI promotes intellectual passivity or lazy copying. Instead, within the context of Social Constructivism, the AI system serves as an interactive "more knowledgeable other" or an automated foil. It generates options that stimulate meta-linguistic critique.

Because Vietnamese and English have completely different structural characteristics (such as topic-prominence vs. subject-prominence), AI translations frequently sound unnatural or structurally flawed. The data shows that students do not simply accept these answers. Instead, the flaws in AI outputs act as an instructional scaffold, prompting students to negotiate meaning, verify rules, and justify their final editing choices.

4.2 Student Engagement and Motivation

Survey data revealed that a substantial proportion of students reported active participation and heightened interest when AI was incorporated into TMT exercises. While only a minority selected an unqualified affirmative response, the majority indicated partial engagement, suggesting cautious optimism rather than uncritical acceptance.

4.3 Collaboration and Critical Inquiry

For RQ3, students demonstrated moderate levels of peer collaboration and inquiry into AI outputs. Notably, a significant percentage reported asking questions or seeking clarification, indicating that AI use did not entirely suppress critical engagement.

4.4 Perceived Learning Improvement

Also for RQ3, more than half of the respondents reported partial improvement in working with TMT exercises through AI engagement. This finding underscores the importance of instructional mediation: AI alone does not guarantee learning gains.

4.5 Instructional Framework for AI-Assisted Structural Translation

This study is grounded in social constructivism (Vygotsky, 1978), cognitive load theory (Sweller et al., 2019). AI functions as a mediational scaffold that reduces extraneous load while stimulating collaborative knowledge construction and critical evaluation. Within transinterpretation pedagogy, learning emerges through guided interaction with AI outputs, where instructor editorial intervention ensures structural rigor and interpretive competence.

4.6 Structure Selection

Also for RQ2, effective exercise design begins with careful selection of grammatical structures aligned with course objectives. Structures such as *inversion, participle clauses, modal perfects, and cleft sentences* were identified as pedagogically valuable. Structures deemed overly basic were excluded to maintain cognitive challenge.

4.7 Vocabulary Domain Selection

To enhance authenticity and motivation, domain-specific vocabulary—particularly from criminal law—was integrated. This thematic focus allowed students to engage with socially relevant content while practicing complex structures.

4.8 Phrasal Verbs as Motivational Catalysts

Also for RQ2, phrasal verbs were incorporated as lexical focal points due to their semantic opacity and high communicative value. Their inclusion increased task difficulty in ways that AI could not trivially resolve.

4.9 Editorial Enhancement

Instructor editing transformed AI-generated sentences/paragraph into linguistically rich, contextually grounded tasks. This step proved essential for preventing monotony and fostering deeper cognitive processing.

5. DISCUSSION

This chapter synthesizes the empirical findings derived from the Principal Component Analysis (PCA) and the descriptive statistical data to provide a comprehensive, critical evaluation of how artificial intelligence (AI) functions within Translation and Machine Translation (TMT) pedagogy.

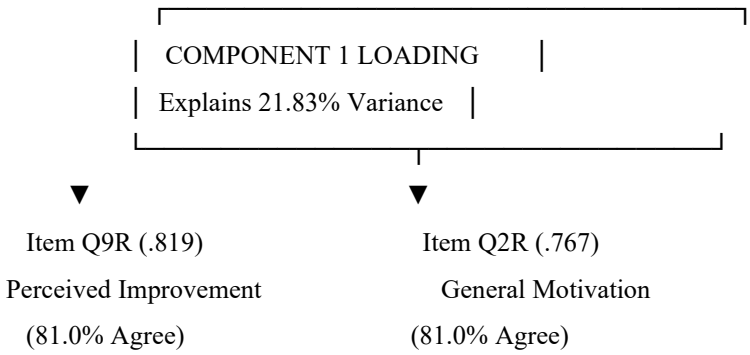
By merging the underlying mathematical factor structure with students' explicit behavioral responses, this discussion bridges the gap between statistical groupings and real-world pedagogical dynamics.

5.1 The Latent Dimensions of AI-Facilitated TMT Learning

The PCA optimized the original 10-item instrument into a refined, highly stable 3-factor framework that explains 58.85% of the total variance. Rather than analyzing survey questions in isolation, this factor structure exposes the underlying cognitive, affective, and behavioral frameworks that govern how university students interact with educational AI.

TOTAL VARIANCE EXPLAINED: 58.85%		
Component 1	Component 2	Component 3
Active Growth & Positive Adoption	Dynamic Motivation & Critical Inquiry	Individualization vs. Collaborative Peer Teamwork
(21.83%)	(18.95%)	(18.07%)

The data distinctly groups into three core dimensions:



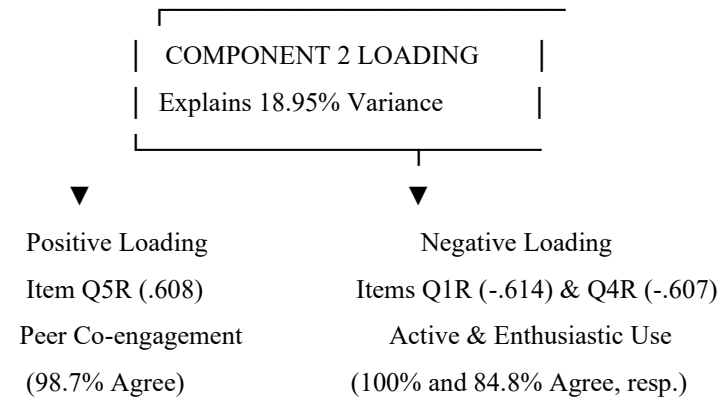
Component 1 (Active Growth and Positive Adoption): Captures the direct link between user satisfaction, engagement, and perceived competence gains.

Component 2 (Dynamic Motivation and Critical Inquiry): Highlights a sophisticated cognitive landscape where intense personal motivation coexists with systemic skepticism.

Component 3 (Individualization vs. Collaborative Teamwork): Reveals the primary pedagogical tension of the AI era—the structural friction between solo human-AI interactions and traditional peer collaboration.

5.2 Component 1: Active Growth and Positive Adoption

Component 1 explains the largest share of post-rotation variance (21.83%) and is strongly defined by Q9R (.819) and Q2R (.767). This statistical alignment reveals that students do not view skill improvement and general motivation as separate outcomes; rather, they form a singular, interconnected dimension of the learning experience.



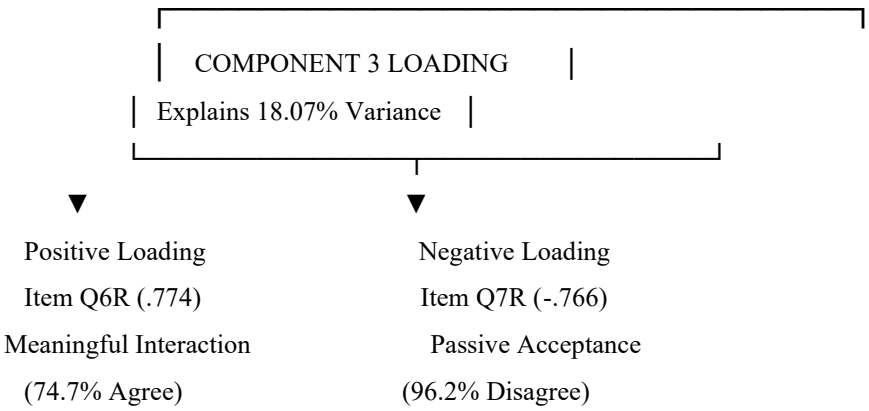
The descriptive statistics strongly support this. A substantial 81.0% of respondents reported clear perceived improvements in executing TMT exercises through AI engagement (Q9R), a figure that mirrors the 81.0% agreement rate for general interest and motivation (Q2R).

This uniform distribution indicates that AI tools provide an immediate linguistic scaffold—offering rapid vocabulary expansions, alternative syntactic structures, and real-time stylistic variations. This immediate validation loop accelerates the transition from abstract translation theory to practical application, directly fueling student confidence and intrinsic morale.

Furthermore, during the item-reduction process, Q10R (active application of AI feedback to improve performance, 98.7% agreement) exhibited a low extraction communality (.355) in the initial 10-item pool, meaning its overwhelming consensus was so absolute that it acted as an ambient, foundational baseline across the entire cohort rather than a variable factor.

5.3 Component 2: Dynamic Motivation and Critical Inquiry

Component 2 (18.95% of variance) presents a highly sophisticated, bipolar cognitive profile. It groups Q5R (.608) positively alongside the negative loadings of Q1R (-.614) and Q4R (-.607).



To interpret this matrix accurately alongside the descriptive data—where active participation (Q1R) reached a flawless 100% positive consensus and personal enthusiasm (Q4R) stood at 84.8%—this structural inversion indicates that intense personal engagement operates in a distinct, converse orientation to basic, task-compelled group presence (Q5R, 98.7%).

More importantly, this dimension reflects a student body that is highly motivated precisely because they are cognitively challenged. The descriptive data in Section 5.4 underscores this sophisticated critical posture: 78.4% of students actively verify AI outputs for accuracy (Q8R), while an overwhelming 96.2% reject passive, unthinking text adoption (Q7R).

The negative/positive polarizations within this component prove that students do not treat AI as an effortless shortcut to bypass thinking. Instead, they interact with the technology as an adversarial cognitive partner, using its machine-generated text as a tentative hypothesis that provokes rigorous error analysis, comparative linguistic judgment, and post-editing scrutiny.

5.4 Component 3: Individualization vs. Collaborative Teamwork

Component 3 (18.07% of variance) isolates the most critical pedagogical challenge revealed by the PCA, characterized by a sharp polarization between Q6R (.774) and Q7R (-.766).

While students strongly agree that their coursework structures compel them to operate in groups alongside AI (Q5R at 98.7%), the actual depth of meaningful interaction and teamwork (Q6R) registered the lowest direct agreement rate in the dataset at 74.7%, alongside the highest level of uncertainty (22.8% neutral responses).

The inverse statistical relationship between meaningful peer teamwork (Q6R) and passive text acceptance (Q7R) exposes a major risk of AI integration: the formation of isolated student-AI dyads.

Because large language models provide highly personalized, instantaneous, and responsive feedback loops, they can easily fulfill a student's immediate cognitive needs. This efficiency inadvertently reduces the perceived necessity of consulting classmates.

Consequently, while students are physically sitting in groups or working on the same assignment, their actual cognitive processing becomes highly individualized. Unless collaborative workflows are intentionally designed to require human-to-human debate, peer interaction risks degrading into superficial task-sharing rather than deep, social-constructivist learning.

5.5 Pedagogical Implications and Summary

The empirical evidence soundly refutes old-school assumptions that student responses to GenAI are defined by hesitation, confusion, or passive reliance. Instead, the data reveals a high-consensus, technologically literate cohort capable of balancing enthusiastic adoption with rigorous quality control.

To maximize the value of these findings, translation instructors must shift away from defensive, restrictive policies and embrace AI-assisted workflows.

6. CONCLUSION

To provide the responses to the research questions, we humbly interpret as follows: This study demonstrates that the pedagogical integration of artificial intelligence into Transinterpretation (TMT) instruction can generate meaningful improvements in student motivation, engagement, and perceived competence when implemented within a structured instructional framework. Survey findings reveal that AI does not automatically produce learning gains; rather, its effectiveness depends on deliberate task design, instructor mediation, and editorial refinement. The predominance of “partial” responses across engagement and improvement indicators suggests that AI functions most productively as a cognitive scaffold rather than a substitute for human expertise.

By aligning AI-assisted structural translation exercises with complex grammatical structures, domain-specific vocabulary, and process-oriented evaluation, the study proposes a balanced model that preserves academic rigor while embracing technological innovation. Although limited in scale, the findings provide preliminary empirical support for a human-centered, AI-assisted transinterpretation pedagogy that responds to institutional innovation demands and evolving professional expectations in Vietnamese EFL contexts. The high rates of critical inquiry justify moving away from restrictive, anti-AI policies. Instead, universities should adopt a human-in-the-loop approach where instructors curate complex lexical challenges (such as phrasal verbs and criminal law terminology) that force students to critique and improve AI outputs.

6.1 Limitations and Future Research

This study is limited to a single institutional context and relies partly on self-reported data. Future research should employ longitudinal designs, controlled experimental comparisons, and cross-institutional samples to validate and extend the proposed framework.

6.2 Pedagogical Implications

-For instructors

Instructors should move beyond merely allowing AI use and instead design structured, cognitively demanding tasks that require analysis, justification, and revision of AI outputs. Editorial intervention, structure selection, and domain-specific vocabulary integration are essential to ensure AI supports—rather than replaces—deep transinterpretative competence.

-For Researchers

Researchers should further investigate AI-assisted translation pedagogy through longitudinal, experimental, and cross-institutional studies. Future research should measure actual performance outcomes, not only self-reported perceptions, and examine how instructional mediation influences the relationship between AI use, motivation, and competence development.

-For institutions

Institutions should develop clear policies that balance AI integration with academic integrity, aligning classroom innovation with assessment standards. Investment in professional development, AI literacy training, and curriculum redesign is essential to ensure technology adoption enhances learning outcomes while preserving unaided competence and examination reliability.

-For Students

Students should treat AI as a cognitive scaffold rather than a shortcut. By critically evaluating, questioning, and revising AI-generated translations, learners can strengthen structural awareness, lexical precision, and interpretive reasoning, thereby developing independent competence necessary for examinations and professional translation practice.

#7 Translation-majored Students' ChatGPT Usage Pattern and Translation Self- Efficacy

Quan Ngo[1], Chau Nguyen[2]

Abstract

AI tools such as ChatGPT have radically transformed the teaching and learning processes. While ChatGPT is widely used, its impacts on learners' confidence and capabilities are concerning. Therefore, this research aims to examine the relationship between translation-majored students' ChatGPT usage patterns and their reported translation self-efficacy. Fifty-five students majoring in Translation were involved in a three-part survey which includes questions on demographic information, common ChatGPT usage patterns in doing translation tasks, and the self-efficacy levels adapted from the Translating Self-Efficacy Scale (TSE-C). Differences in translating self-efficacy among groups of users with different ChatGPT usage patterns were analyzed using one-way ANOVA, followed by Games-Howell post-hoc tests for pairwise comparisons. The findings reveal higher confidence among students using ChatGPT to analyze and plan their translation tasks compared to those who used ChatGPT for drafting translations. The study results inform lecturers' instructional design, thus guiding students to effectively use AI tools and develop self-efficacy in translating tasks.

Keywords**:** *ChatGPT, ChatGPT usage patterns, translation self-efficacy*

1. Introduction

AI has become increasingly significant in education with its relevance in language learning and translation. There are numerous AI tools available today; however, ChatGPT has gained much popularity because of its ability to provide responses like human beings and provide quick support for educational activities. In translation learning, students use ChatGPT not only to search for information but also to understand vocabulary, explore cultural meanings, revise their translations, and create translation drafts. According to Ngo (2023), ChatGPT is an advanced natural language processing system that supports users through interactive communication. Therefore, the application of AI-based translation has become more widespread today.

The growing use of ChatGPT entails both benefits and concerns. Firstly, AI software can help learners acquire language skills and improve their efficiency in handling translation tasks (Nguyen et al., 2025). Students may feel less anxious while dealing with complex texts since AI will give them immediate explanations. However, some specialists point out that relying too much on ChatGPT will make students less independent and unable to build their translation skills (Ma, 2024; Nguyen et al., 2025). Instead of analyzing texts and solving the problem themselves, students will become too dependent on computer-generated results, which negatively impacts students' self-efficacy.

In translation pedagogy, students' translating self-efficacy revolves around their confidence in grasping the source text, diagnosing the challenges of the translation, coming up with the solutions to overcome the challenges, and carrying out effective translation. Many

[1] *School of Languages, International University, VNU HCM, Vietnam; Email: ngophamtuongquan@gmail.com*
[2] *Corresponding author, School of Languages, International University, VNU HCM, VietNam; Email: ntnchau@hcmiu.edu.vn*

previous studies concentrated on the significant effects of self-efficacy on the students' motivation, persistence, and performance (Yang et al., 2021; Yuan et al., 2024). Stronger self-efficacy is associated with the students' willingness to face challenges and the ability to work alone. Although numerous studies examined AI-assisted learning and translation competence, few addressed the connecting point between students' utilization of ChatGPT and their translating self-efficacy. As ChatGPT is seemingly morphing to become more of a common part of translation, looking into this relationship is critical for educators and researchers.

Thus, the study explores how students are using ChatGPT for translation and how translating self-efficacy manifests in students with diverse usage patterns. The study employs Borg's (2018) translation process as well as the Human-AI Writing Continuum by Rowland (2023) to analyze students' AI-assisted translation activities.

This study seeks to answer the following research questions:

1. How do students use ChatGPT in translation practices?
2. To what extent do the levels of translating self-efficacy differ across students with different ChatGPT usage?

2. Literature Review

2.1. Translation Self-Efficacy

Bandura (1997) described self-efficacy as self-judgment of the capacity to perform a task that demands one's skill set. Also, these self-beliefs generally play a part in shaping the approach, persistence as well as cognitive and emotional responses to a challenge (Bandura, 1995). Therefore, efficacy beliefs, as well as skills, are required for appropriately performing functions (Bhati & Sethy, 2022). In translation, the term "translation self-efficacy" refers to the confidence of a student in their ability to complete a translation project (Yang et al., 2021). This concept includes the ability to understand, solve problems, make decisions, and produce written output during translation, in addition to the ability to use language effectively.

Research in translation education shows that students with strong self-efficacy are more willing to tackle difficult texts, try out different strategies, and learn from feedback. Self-efficacious people address challenges without much dependence on outside help (Bolaños-Medina & Núñez, 2018). Students who trust their abilities are also more likely to develop self-regulated learning and professional confidence (Liu & Yu, 2019).

Yang et al. (2021) developed the translating self-efficacy scale (TSE-C) - a tool for non-native English speakers, including language learners, translation students, and non-language learners who wish to gain translation skills in preparation for a career as translators. The TSE-C scale is based on Bandura's (1997) self-efficacy framework but is specifically adapted to the actual translation competence required. The TSE-C scale consisted of 15 items grouped into three connected domains: Internal Competence, Psycho-physiological Competence, and External Competence. While Internal Competence (IC) depicts students' confidence in their language proficiency and abilities to solve translation-related problems, the Psycho-physiological Competence (PPC) reflects emotional and physiological factors that impact translation performance like managing stress and self-regulating. The last domain refers to students' confidence in handling external aspects of translation like using resources, managing time and communicating with teachers or clients (Yang et al, 2021).

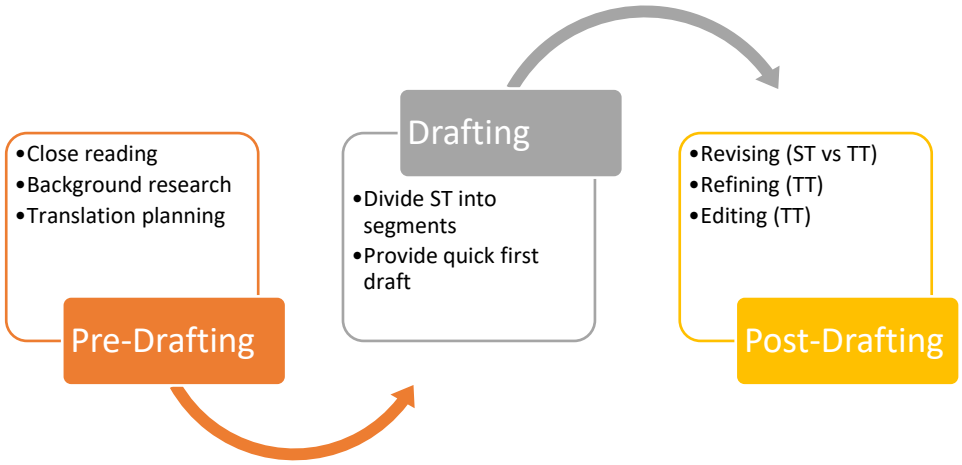
Translation performance is considered non-linear because it involves many different layers, including contextual factors and individual learner characteristics. Instead of focusing

only on objective test results, the TSE-C scale pays attention to learners' self-concepts and provides valuable insights into the relationship between confidence, motivation, and self-regulation. In this way, it helps explain how learners develop translational competence. Therefore, TSE-C is an appropriately developed scale designed to systematically measure these individual differences.

Self-efficacy also affects how student translators analyze texts, make decisions, revise their translations, and use technology tools, including AI systems such as ChatGPT, during different stages of the translation process. In this context, ChatGPT can support students throughout the translation process and help strengthen their confidence.

2.2. Borg's (2018) Translation Process

Translation can be viewed as a complex task involving multiple stages of translation. In the first stage of the translation process, the translator spends a significant amount of time becoming acquainted with the source text (ST). Acquaintance is achieved through a close reading of the ST, background research, and translation planning. Borg (2018) demonstrated that before the translator even starts on a draft, the translator reads the ST through several times and immerses themselves in the context, using dictionaries and other sources. This is important because studies have shown that some translators do not read the full text in advance (Borg 2018). The goal during this first phase is to make sure the translator fully comprehends the ST.



The next stage was the drafting stage. Borg (2018) stated that the translator divides the ST into smaller work units, used only a few external resources, and produces a quick first draft of the TT. Drafting and revising are distinct stages, unlike older approaches to translation, which would have done both simultaneously.

The translator then takes some time away from the draft and begins the last stages which involves: revising, refining, and editing. In the revision one, the translator goes over the text several times, consulting dictionaries and other works and rewriting passages when necessary. This stage involves close comparison of the source and target texts. The next one concentrates on refining the artistic manner of the target text (TT). Within this period, the focus moves toward the target text (TT) instead of the source text (ST). The translation professional improves the artistic manner, selection of words, coherence, spelling, and punctuation. The final one involves careful reading for errors. The translation professional reads the writing with a loud voice so that the rhythm and human flow of the language can be confirmed. Small fixes are performed by the translation professional before the work is sent. Borg (2018) states that translation professionals do not usually return to the source text (ST) during this final stage. A focus on the natural quality and the ease of reading of the target text (TT) is maintained instead.

According to Borg (2018), the number of translating phases is subject to individual translators and may not be limited to a certain number, specifically three phases as commonly confirmed in previous studies (Mossop, 2000). However, in the current study which examines students' ChatGPT use behaviors, the three phases after drafting share the underlying utilization pattern of the AI tool, so they are referred to as Post-Drafting in this study.

Figure 1

Translation Process

2.3. ChatGPT and the Application of ChatGPT in Translation

ChatGPT is based on Generative Pretrained Transformers (GPT; Brown et al., 2020; OpenAI, 2023) and trained using the Reinforcement Learning from Human Feedback (RLHF). As a result, it can generate natural responses, answer questions, and support ongoing interaction. With a large amount of human-written data, such as books, articles, reviews, and online discussions, the model was trained to recognize language patterns and respond to different topics more humanlike, thus being widely used in language-related tasks, including translation (Wang et al., 2023). With ChatGPT's assistance, students can explore difficult source texts before drafting, generate translation suggestions, and identify errors of the translations (Brahmana et al., 2025; Nguyen 2024). ChatGPT was also recognized as a useful tool for students to revise their translated text by prompting the AI tool to provide feedback on their translations (Yang et al., 2025) or to create alternative versions to evaluate different styles of translation (Nguyen, 2024).

The level of AI involvement in translating, however, varies among students. Some mainly use it for background research or improving language quality, while others rely on it more heavily to complete translation tasks. This also leads to the problem of students relying too much on ChatGPT to perform the entire translation process, completely replacing humans, instead of just using it as a support tool. Scholars caution that AI-assisted workflows risk diminishing translators' autonomous decision-making if used passively or uncritically (Pym, 2014). As a result, examining students' AI usage patterns requires a comprehensive model that depicts students' different levels of AI involvement in doing translation tasks.

2.3 The Human-AI Writing Continuum

Rowland (2023) proposed the Human-AI Writing Continuum to model the relationships between human writers and AI tools in writing. This continuum provided a basis to establish the Human-AI Translating Continuum, which is the continuum used in this research. At one end is human-led where no AI is used (level 1), while at the other end is AI-led, where most of the text is generated by AI (level 9).

Between these two endpoints exist several types of human-AI interaction. They include writing guided by AI, wherein the artificial intelligence assists generating ideas; writing assisted by AI, in which AI helps construct sentences and provide linguistic input; and

collaborative writing, where human beings and AI work together during the writing process. This model underscores the nonlinear and highly contextual nature of human-AI interaction.

The continuum model is significant because it illustrates that the association between man and machine is dynamic and highly situational. For this study, the model would be used to determine how students use ChatGPT when translating. For instance, students could use ChatGPT to look up cultural words and concepts but become more independent during drafting and revising. By placing students' behaviors along the continuum, the study can better understand patterns of AI use, levels of dependence, collaboration strategies, and their possible influence on translation self-efficacy.

2.4. Research gaps

Previous works have explored mostly machine translation systems and CAT tools but have rarely looked at conversational AI like ChatGPT and its relationship with translation learning and self-perceptions. Similarly, research on the usage of ChatGPT in education has mostly covered academic writing, rather than translation learning. Accordingly, further research is still necessary to uncover how student translators are using ChatGPT and how this usage relates to their translation self-efficacy. The present study thus intends to examine the relationship between ChatGPT use and translation self-efficacy in student translators.

2.5. Conceptual Framework

The Rowland's (2023) Human-AI continuum and Borg's (2018) translating process are adopted to depict the dynamic roles of ChatGPT and human in translation tasks. Instead of treating AI use as a simple "use or not use" issue, the continuum presents a range of interactions in which human contribution and AI assistance vary throughout the translation process. Based on nine levels of Rowland's continuum, the current study's seven levels were adopted to represent different patterns of students' ChatGPT usage during translation tasks. Because translating tasks do not require students to generate new ideas, level 4 of the original continuum was adapted into "Students ask ChatGPT to analyze the assignment topic, explore background information or cultural context, clarify difficult terms, idioms, or technical vocabulary before translating. However, the student translates and reviews the final version." The nature of the level was maintained with AI assistance in content analysis and human's control of the translating/writing task. The original levels 6 and 8 were omitted as they are closely related to writing tasks and may not reflect the nature of translation. Specifically, paraphrasing ideas from other sources and generating external texts, e.g. an abstract for student-written paper, are not relevant to translating tasks, thus being removed. The seven remaining levels are adapted and mapped with the proposed translating process as demonstrated in table 1.

Table 1

Levels of Interaction with AI in Translation Phases

Level	Description	Translating Phase wherein AI is used
1	Students perform all tasks independently, including reading and analyzing the source text, making lexical and stylistic decisions, drafting and revising the target text, and completing quality checks without AI input.	None
2	As per level 1, but students use ChatGPT to correct grammar, vocabulary, or spelling.	Post-Drafting

3	As per level 1, but ChatGPT is asked for feedback on how the student translation can be improved. Students adopt or adapt recommended changes.	Post-Drafting
4	Students ask ChatGPT to analyze the assignment topic, explore background information or cultural context, clarify difficult terms, idioms, or technical vocabulary before translating. However, the student translates and reviews the final version.	Pre-drafting
5	Students use ChatGPT to translate the whole text, then they review the output and edit it by themselves.	Drafting
6	ChatGPT generates the first draft translation. After that, the student has a "conversation" with ChatGPT until they can achieve the best version.	Drafting
7	Students adopt without change, and ChatGPT is in the role of translating the whole translation task.	All

Combining these two frameworks allows researchers to examine both the stages in which students use ChatGPT and the extent of AI involvement during translation tasks. The Pre-Drafting stage aligns with Level 4 of the Human-AI Continuum, in which students apply ChatGPT to get a summary, search for backgrounds, and promote their comprehension, and they translate texts on their own. In this stage, AI works as a tool of support instead of substitution. The Drafting stage includes Levels 5 and 6, where ChatGPT plays a larger role in generating translations. Students revise and edit the AI-generated output based on their own linguistic competence. At Level 6, students repeatedly prompt ChatGPT to revise translations. The last translation phase corresponds to Level 2 and 3, in which students mainly adopt ChatGPT to provide feedback and suggestions. These typologies help explain students' behaviors of using ChatGPT and facilitate in comparing translation self-efficacy differences across different AI user groups.

3. Methodology

3.1. Study design and Participants

This study employs a quantitative design to explore the relationship between translation-majored students' ChatGPT usage in translating texts and their translation self-efficacy. Data analysis was conducted using descriptive statistics and one-way ANOVA analysis in Jamovi – an open statistical software. The research is divided into two parts: the first part deals with how students used ChatGPT when performing translation tasks, and the second part explores how students rated their confidence when performing the translation task without ChatGPT assistance.

The sample of this study includes 55 students selected from the population of English-majored students from a university in Vietnam. However, two responses were removed for two reasons: (1) one student reported no AI use in their translating practice, so this response is not related to the research questions; and (2) according to standard course sequencing and prerequisite requirement, one student response shows a mis-match between the year of study and the taken translation courses, so their answer is considered not reliable. As a result, there are a total of 53 participants. All of them have or have been taking translation courses as part of their academic program, ensuring a shared foundation in translation theory and practice.

3.2. Instrument:

A Google Forms survey was used to gather data on students' ChatGPT usage and translation self-efficacy. The survey with the three distinct parts completely addressed the objectives of the study.

The first section contains questions about participants' background and demographics, including students' year of study, the number of translation courses they had taken, and their self-assessed English proficiency based on the CEFR framework.

Then, students selected their usage pattern, or the most suitable way of using ChatGPT to translate texts, among seven predetermined options following the Human-AI Translating Continuum, ranging from not using ChatGTP to completely relying on this AI tool.

The third section adapted Yang et al.'s (2021) Translating Self-Efficacy Scale with Likert-scale items that evaluated Internal, Psycho-physiological, and External Competence.

The validity and reliability of the instrument was strengthened by implementing a pilot study and adapting Yang et al. (2021)'s validated scale.

Section 2 of the questionnaire were adapted based on the emergent frameworks of Borg's Translation Process and Rowland's (2023) Human-AI writing continuum. A pilot study with 12 senior students who have participated in compulsory and elective translation courses was conducted. Their examples of ChatGPT prompts were used to identify any ChatGPT usage pattern which was not included in the section 2 of the questionnaire. For example, participant 9 of the pilot study explained their ChatGPT usage as follows.

I paste the whole text I already translated as well as the source textand ask Chat GPT "Please evaluate my translation compared to this source text following the rubrics: Grammar Accuracy, Vocabulary Use, and How compatible of the two texts. Also, please provide some improvements related to cultural differences for my translation, clafifying that whether the target language can fully interpret the source language but the target readers can still understand what the translation is about."

The explanation matches with option 3 in the list of 7 ChatGPT usage pattern which states "I do the task by myself, then use ChatGPT to give feedback on the quality of translation, and I adapt the recommended changes". The pilot study did not reveal any using behavior that cannot be matched with the 7 predetermined usage patterns of the questionnaire, which confirms the validity of section 2.

Regarding section 3, the scale was mainly adapted from Yang et al.'s (2021) Translating Self-Efficacy Scale. Before Yang et al. (2021) developed the TSE-C scale, there were a lot of preliminary scales measuring students' translating confidence in translation, such as the scales developed by Stansfield et al. (1992), Bolaños-Medina and Núñez (2018), and Konttinen (2021). However, each of these scales had certain limitations. Stansfield et al. (1992) introduced what was considered the first "translation ability self-assessment questionnaire" (as cited in Abdel Latif & Alhamad, 2025). The scale mainly measured students' perceived ability to complete translation tasks, but it did not include important translation competencies. Another limitation was the lack of validation data in the published study. Later, Bolaños-Medina and Núñez (2018) developed the first standardized translation self-efficacy scale. However, their research focused mainly on English–Chinese translation and used a relatively small sample size. Konttinen's (2021) scale was developed more recently, but it focused on students' self-efficacy in translation company simulations rather than translation practice in educational settings. Taking all the above considerations and gaps of previous translating self-efficacy, the scale by Yang et al. developed in 2021 met all the requirements. The translating self-efficacy

scale (TSE-C) is a valid and dependable tool for non-native English speakers, including language learners, translation students, and non-language learners who wish to gain translation skills in preparation for a career as translators. The TSE-C scale is based on Bandura's (1997) self-efficacy framework but is specifically adapted to the actual translation competence required. It views translation self-efficacy as something complex and multilayered that affects students' level of confidence in their ability to translate well.

To ensure the reliability of the Translating self-efficacy scale, reversed items were added into the last construct, External Competence, in order to test if participants pay sufficient attention to reading items and choosing responses. Cronbach's alpha was measured, and items were removed to ensure the internal consistency.

Efficacy in…	Cronbach's Alpha	Removed Items	Updated Cronbach's Alpha
Internal Competence (IC)	.773	IC2	.805
Psycho-physiological Competence (PC)	.562	PC5	.810
External Competence (EC)	.610	EC4	.667

The final version of Translation self-efficacy scale, therefore, includes 12 items with 6 items measuring efficacy in Internal Competence, 2 items for Psycho-physiological Competence, and 4 items for External Competence.

3.3. Data analysis

The data were analyzed using Jamovi to examine differences in translation self-efficacy among students who used ChatGPT for translation in three different stages: Pre-Drafting, Drafting, and Post-Drafting. Descriptive statistics including the frequency and percentage of Agree and Strongly Agree options were reported to provide an overview of students' confidence when translating without using ChatGPT.

A one-way ANOVA was then conducted to compare translation self-efficacy across three groups of ChatGPT usage. In Jamovi, the dependent variable was labelled as TSE (Translating Self-Efficacy score), which is the sum of participants' answers for 12 items adapted from Yang et al. (2021). The independent variable was labeled as ChatGPT_Stage and consisted of three groups formed from seven predefined usage patterns based on the Human–AI Translating Continuum and Borg's (2018) Translation Process model.

4. Results

4.1. Descriptive Analysis of Variables

Most participants (53 out of 54) employed ChatGPT to assist their translation process; however, the data indicates that students employed ChatGPT in vastly different ways when working on their translation tasks. No students used ChatGPT to do the whole translation without any human input, while others utilized the AI tool in different stages.

Table 2

ChatGPT Usage Pattern

ChatGPT is used in	Frequency	Percentage
Pre-Drafting	22	41.51%
Drafting	20	37.74%
Post_Drafting	11	20.75%

The two largest groups of students used ChatGPT for Pre-Drafting and Drafting phases, with 41.51% and 37.74% of participants, respectively. Most students used ChatGPT in the Pre-Drafting phase to explore background information, cultural context, or difficult vocabulary before translating the text independently. A significant part of students (20.75%) employed ChatGPT for revising and editing while producing the draft on their own. However, a large proportion of participants used ChatGPT to generate draft translations and then reviewed as well as edited the output themselves or with ChatGPT assistance. Overall, the finding suggests that most students viewed ChatGPT as a support tool rather than a replacement for translation. In other words, a more balanced and supportive use of ChatGPT was frequently employed rather than using generative AI tools exclusively or minimally.

Table 3

ChatGPT Usage Pattern by English Proficiency

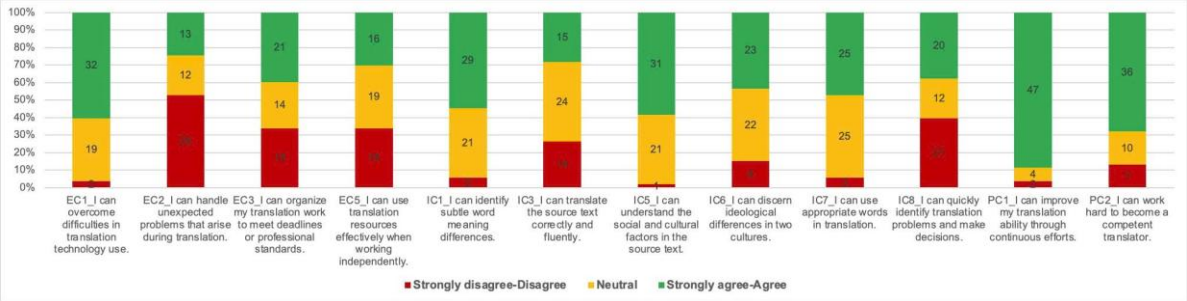
Proficiency	Total Number	Pre-Drafting	Drafting	Post_Drafting
B1	5	40.00%	40.00%	20.00%
B2	17	29.41%	41.18%	29.41%
C1	29	51.72%	34.48%	13.79%
C2	2	0.00%	50.00%	50.00%

As the number of participants with B1 annd C2 levels are relatively limited compared to the other two, their responses should be considered with caution. Regarding the two largest groups of participants, the ones with higher proficiency (C1) has a larger proportion of students using ChatGPT for the Pre-Drafting stage while the B2 group tend to rely on ChatGPT for Drafting.

Table 4

ChatGPT Usage Pattern by Translation Experience (via taken translation courses)

Translation Experience	Total Number	Pre-Drafting	Drafting	Post-Drafting
COMPULSORY	38	50.00%	36.84%	13.16%
COMPULSORY_ELECTIVE	15	20.00%	40.00%	40.00%



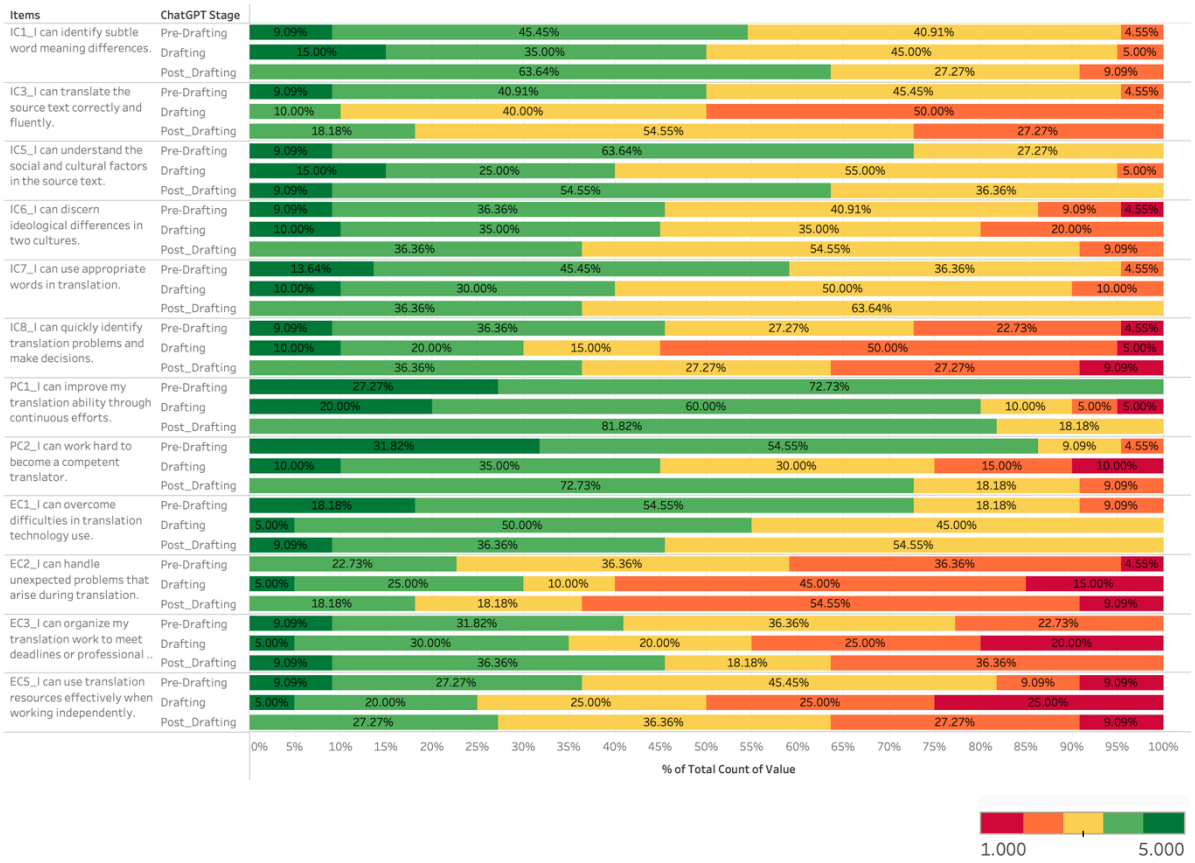
There are significant differences between the utilization of ChatGPT in the Pre-Drafting and Post-Drafting of the two groups. While those with lower exposure to translation courses

(only taking compulsory translation courses) mainly used ChatGPT for Pre-Drafting, the more experienced group tend to depend on ChatGPT for Drafting and Post-Drafting. As Post-Drafting is the stage with limited ChatGPT use compared to the other two, this remarkable tendency among the experienced group gives an insightful perspective on students' ChatGPT using behavior.

Participants' self-reported Translating Self-Efficacy (TSE) varied across dimensions, including Internal Competence (IC), Psycho-physiological Competence (PC), and External Competence (EC). Reversed items have been reworded for consistent reporting.

Figure 2

Frequency of TSE Responses



Overall, the results indicate that students reported relatively high levels of translation self-efficacy (TSE), as most responses were concentrated in the "agree" and "strongly agree" categories across items. Higher levels of confidence were particularly evident in items related to translation improvement and self-assessment (PC1, PC2, EC1), where a large majority of respondents selected positive response options. However, confidence was comparatively lower when encountering external challenges (EC2, EC3, EC5) or tasks requiring cognitively demanding skills such as translating source texts correctly and fluently (IC3), as well as identifying and solving translation problems (IC8).

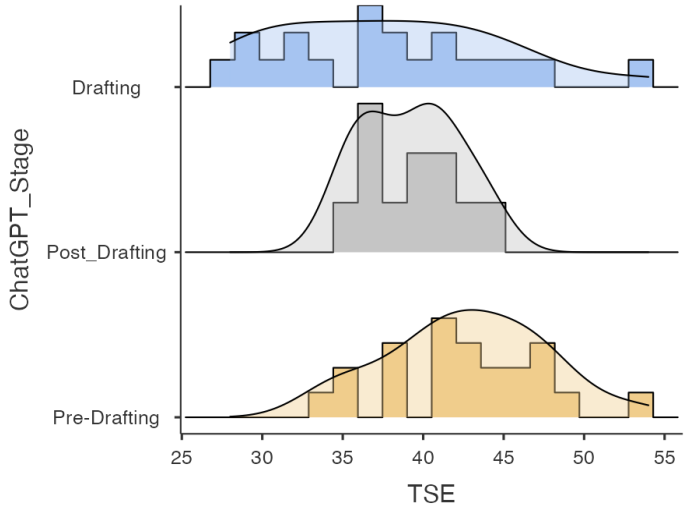
The TSE responses also followed divergent patterns across three ChatGPT usage groups, namely those use ChatGPT in the Pre-Drafting, Drafting and Post-Drafting stages.

Figure 3

Frequency of TSE Responses by ChatGPT Usage Groups

Users of ChatGPT for Pre-Drafting demonstrated the strongest confidence levels. For most items, they consistently exhibit the largest percentages of positive responses and lowest percentages of negative evaluations, whereas Drafting and Post-Drafting users displayed more varied response patterns. Negative responses are limited across ChatGPT usage groups except for some special cases. Specifically, Drafting and Post-Drafting groups' answers to EC2 (I can handle unexpected problems that arise during translation), Drafting groups' answers to EC5 (I can use translation resources effectively when working independently), IC3 (I can translate the source text correctly and fluently) and IC8 (I can quickly identify translation problems and make decisions) include a substantial amount of negative choices (more than 50%). More than a third of Post-Drafting participants also reported low confidence in EC3, EC5, and IC8. Nevertheless, in general, positive perceptions dominated across all groups, suggesting that students generally felt capable of performing translation tasks regardless of how they incorporated ChatGPT into their translation process. Their total TSE scores – calculated by adding up scores for 12 items – can be summarized as follows.

Table 5



TSE Scores across ChatGPT Usage Groups

	ChatGPT_Stage	N	Missing	Mean	Median	SD	Minimum	Maximum
TSE	Pre-Drafting	22	0	42.7	43.0	4.84	34	53
	Drafting	20	0	37.8	37.0	7.01	28	54

ChatGPT_Stage	N	Missing	Mean	Median	SD	Minimum	Maximum
Post_Drafting	11	0	39.2	40	2.99	35	44

Figure 4

TSE Scores Distribution across ChatGPT Usage Groups

4.2 One-way ANOVA Results

Based on the ChatGPT usage patterns, a one-way analysis of variance (ANOVA) was conducted with the dependent variable being the translating self-efficacy score (TSE) and the independent variable being the 3 groups of ChatGPT usage patterns (Pre-Drafting, Drafting, Post-Drafting). First, Levene's and Shapiro-Wilk tests were conducted to test the assumption of homogeneity of variance and normality across groups.

Table 6

Assumption Checks

Normality Test (Shapiro-Wilk)

	W	*p*
TSE	0.979	.462

Homogeneity of Variances Test (Levene's)

	F	df1	df2	p
TSE	4.14	2	50	.022

Shapiro-Wilk were not statistically significant (p = .462 >.05), indicating normally distrubted data. However, Levene's test is below the .05 threshold, revealing violated homogeneity of variance (p = .022). As a result, Welch's ANOVA and Games-Howell were used for the data analysis instead of Fisher's and Tukey's HSD. The results of the ANOVA analysis are presented in Table 5 below:

Table 7

ANOVA Results for Differences in Translating Self-Efficacy Across ChatGPT Usage Levels

One-Way ANOVA (Welch's)

	F	df1	df2	p
TSE	4.60	2	31.8	.018

The results showed the statistically significant difference in translating self-efficacy levels between the groups using ChatGPT (p = .018). This suggests that differences in translating self-efficacy levels are associated with different levels of students' use of ChatGPT.

Table 8

ANOVA Post-hoc Comparison of Translating Self-Efficacy Across ChatGPT Usage Levels

Games-Howell Post-Hoc Test – TSE

		Drafting	Post_Drafting	Pre-Drafting
Drafting	Mean difference	—	-1.38	-4.88
	p-value	—	.728	.036
Post_Drafting	Mean difference		—	-3.50
	p-value		—	.042
Pre-Drafting	Mean difference			—
	p-value			—

Games-Howell post-hoc analysis showed a statistically significant difference in translating self-efficacy between Pre-Drafting and Drafting (p = .036), with students using ChatGPT in the Pre-Drafting phase reporting higher translation self-efficacy. The choices of using of ChatGPT in the Pre-Drafting or the Post-Drafting phases also correlate with the different levels of translating self-efficacy (p = .042). In both cases, students using ChatGPT in Pre-Drafting reported higher level of confidence compared to those employing ChatGPT for the Drafting and Post-Drafting phases. The TSE scores of Drafting and Post-Drafting showed no significant differences (p = .728 > .05).

Further ANOVA tests were run with independent variable being the proficiency and the taken translation courses respectively. Both tests reveal insignificant statistical differences in TSE among these groups. The results are presented as follows.

Table 9

ANOVA Post-hoc Comparison of Translating Self-Efficacy Across Proficiency Levels

Tukey Post-Hoc Test – TSE

		B1	B2	C1	C2
B1	Mean difference	—	-0.741	-2.59	-6.80
	p-value	—	.994	.796	.511

5. Discussion

The findings provide insights into how students use ChatGPT during translation tasks and how different usage patterns relate to translation self-efficacy.

5.1. Students Use ChatGPT to Support Their Translation Skills

From the results presented, the students used ChatGPT at different stages of the translation process. The most common stage that was used is the Pre-Drafting stage, which accounts for 41.54% of the total number of students. At this stage, it is mainly used by the students to gather background knowledge, cultural knowledge, or even unknown words before creating their translations. The use of ChatGPT for Drafting stage was examined in 37.74% of the participants, who employed ChatGPT to produce draft translations and then refined the products through either repeated interaction with the AI tools or on their own. Meanwhile, 20.75% of students mainly used ChatGPT during the polishing, fine-tuning, and proofreading stages, utilizing the tool to check errors and provide feedback after students completed their translations independently. Within this general trend, participants with different proficiency and translation experience demonstrate diverse tendencies in ChatGPT using behavior. Specifically, whie the higher proficiency group mostly use ChatGPT for Pre-Drafting, the lower one rely on the AI tool for Drafting. This is understandable as students with higher English proficiency face less challenges in language use and start focusing on ensuring the accuracy, naturalness and appropriateness in their translation. As a result, they prefer more ChatGPT assistance for gathering background and cultural knowledge before translating texts. ChatGPT utilization of participants with different translation experiences also yields valuable insights. The group with lower translation experience mainly use ChatGPT for Pre-Drafting and Drafting. On the other hand, the higher experience group favor the use of AI support in the Drafting and Post-Drafting. This illustrates the students' perception of the translator role. While those with fewer experience consider themselves learners and use AI tools to support the process of enriching knowledge and skills, the one taking more translation courses may have familiarized themselves with the translation process and start assigning tasks to their AI assistance.

Unlike previous studies such as Kaiyi (2025) and Dinh (2025), which identified the revision stage as the most common stage of AI use, this study found that students mainly used ChatGPT during the preparation stages. This suggests that students regarded ChatGPT more as a tool for exploring and organizing knowledge than as a complete translation assistant. These differences may be due to differences in students' backgrounds, language abilities, and learning goals. Overall, the findings reveal ChatGPT's role as a support tool throughout the translation process rather than a replacement for human translators.

5.2. Levels of Translation Self-Efficacy and Differences among Groups of ChatGPT Usage

The descriptive analysis showed that students' translation self-efficacy was overall high in all three dimensions: Internal Competence, Psycho-physiological Competence, and External Competence. Among these three competences, students reported higher confidence in Psycho-physiological Competence and lower in External as well as Internal Competence. Based on this information, students had higher confidence in controlling their efforts, persistence, and emotions rather than in their language, decision-making abilities, and external conditions. The low scores for Internal Competence suggest that students still had difficulty analyzing the language, constructing their own meanings, and solving translation problems. Such a conclusion aligns with the results of Dinh's (2025) study, which found that translators experience difficulties when developing their translation strategies and defending their translation choices.

The one-way ANOVA results also revealed a statistically significant difference in translating self-efficacy among groups with different levels of ChatGPT usage ($p = .018$). Post-hoc analysis showed that this difference was primarily between Pre-Drafting and the other two stages. Students who relied more heavily on ChatGPT for generating translations demonstrated

lower confidence in their own translation abilities than students who used the tool more selectively. Additionally, there are no statistically significant differences between students with different English proficiency and translation experience. The findings suggest that proficiency and experience are not significant factors impacting translation self-efficacy, and excessive reliance on AI may reduce opportunities for independent practice and mastery experiences, which Bandura (1997) identified as an important source of self-efficacy development. The results also echo Zhang and Xu's (2025) paradox of self-efficacy which states leveraging AI can boost students' confidence but at the same time intensifying their AI reliance. As a result, an appropriate level of AI integration in teaching and learning translation is required to ease the negative impact of the paradox. Overall, the findings indicate that careful and critical use of ChatGPT may support translating self-efficacy, while overdependence on AI tools may weaken students' confidence in their own translation competence

6. Conclusion

The present study investigated the relationship between the use of ChatGPT and translation self-efficacy among university student translators. Findings from the TSE-C scale (Yang et al., 2021) and one-way ANOVA analysis showed that different levels of ChatGPT use were linked to differences in students' translating self-efficacy. In general, students who employed ChatGPT strategically and moderately had higher confidence in translation tasks compared to those who heavily relied on AI-generated translations.

The findings also showed that students used ChatGPT in different stages of the translation process. For most participants, they made use of the platform in the Pre-Drafting stage, where they would carry out research about the text, clarify terms, and plan on the best approach to take before embarking on the translation process. The remaining participants resorted to the platform to create translations or for proofreading purposes after creating their own versions. However, different levels of proficiency and translation experience can affect their ChatGPT using behavior.

Regarding translating self-efficacy, students reported moderate levels across the three dimensions of internal competence, psycho-physiological competence, and external competence. Among these, psycho-physiological competence attained the maximum rating because the students felt more competent at putting in effort, persisting, and regulating emotions while undertaking translation. Internal competence, on the other hand, scored the least since the students had problems with linguistic analysis and translation strategy making.

Importantly, the study found significant differences in translating self-efficacy among groups with different ChatGPT usage patterns. The ones who extensively used ChatGPT when translating were less likely to display self-efficacy, while those using the tool moderately, such as for generating ideas and looking up terms, showed more self-confidence. It is possible to infer from the results that moderation in the use of ChatGPT could foster self-efficacy in learners.

The findings also provide several implications for translation education. Teachers should encourage selective and goal-oriented use of ChatGPT rather than allowing students to depend on AI throughout the entire translation process. ChatGPT can be effectively used for brainstorming, terminology clarification, and culture lookup while students remain responsible for the main translation decisions. Universities may also consider providing AI literacy training, including prompt writing, evaluation of AI-generated content, and strategies for revising AI-supported translations. In addition, the study contributes theoretically by combining Borg's (2018) Five-Phase Translation Model with Rowland's (2023) Human–AI

Continuum to better explain the relationship between AI involvement and learner autonomy in translation tasks.

Despite these contributions, the study has several limitations. First, the sample size was relatively small and limited to students from one university, which may reduce the generalizability of the findings. Additionally, because the study relied on self-reported survey data, participants may have underreported their AI use or overestimated their self-efficacy levels.

Overall, the study suggests that ChatGPT can serve as an effective support tool in translation education when used carefully and critically. However, passive or excessive reliance on AI may weaken students' confidence and independence in translation tasks. Therefore, maintaining a balance between AI support and human control is important for developing both translation competence and translating self-efficacy in technology-enhanced learning environments.

#15 From Classroom to Real Life: First-Year Students' English-Speaking Use across Learning Contexts

Nguyen Thi Ngoc Chinh[1]

Abstract

The present study aims to examine the English-speaking practices inside and outside the classroom by first-year Vietnamese university students during their preparatory English program in a non-English-speaking environment. The study sample consisted of 50 lower-intermediate EFL learners at the outset of the program, corresponding to levels A2-B1 on the CEFR scale. In the Vietnamese context, classroom-based English speaking is considered essential for developing oral communication skills, while outside-school real-life use is limited, especially for young university students. This study also sought to examine the relationship between in-class speaking and out-of-school English use. The study employed the explanatory sequential mixed-methods research design. Quantitative data collection methods were employed to address the research questions, including the administration of a structured questionnaire to assess the frequency of English-speaking practices among participants. Additionally, semi-structured interviews were used to gain more insights into the participants' out-of-school use of English. Quantitative data were analyzed through statistical methods, while qualitative data were analyzed through thematic analysis. The findings indicate that the students spoke more English inside the classroom than outside the classroom. Inside the classroom, the students spoke English mainly through structured activities, such as answering teachers' questions, discussing in pairs or groups. On the other hand, the participants rarely used English outside the classroom to communicate in real-life situations. The findings reveal a substantial discrepancy between instructional speaking participation and spontaneous English use in authentic communicative contexts.

***Keywords*:** English speaking, EFL context, first-year university students, classroom and real-life communication, mixed-methods study

1. Introduction

English speaking competence is widely recognized as an essential learning outcome (Richards, 2008; Bygate, 1987) in the context of tertiary English language learning and teaching, especially in the context of English as a Foreign Language (EFL). Within the context of higher education, the relationship between the articulation of ideas in English and student learning outcomes, including academic participation, professional preparedness, and employability, has been widely discussed in previous literature (Richards, 2008). Accordingly, the role of English language learning and teaching in the context of higher education lies in the promotion and development of English-speaking skills, especially in the early stages students' learning pathways.

In EFL contexts such as Vietnam, opportunities for English speaking are largely confined to classroom settings, while real-life communicative use outside the classroom remains limited. Classroom-based English use, including teacher–student interaction, pair work, and group discussions, serves as the primary source of speaking practice for many EFL learners in contexts where opportunities for authentic communication remain limited (Richards, 2008; Littlewood, 2007). These classroom practices are important for the teaching

[1] *English Teacher, FPT University, Hanoi*

of English but are limited to controlled contexts and are not necessarily indicative of the willingness or ability of the students to use English outside the classroom.

Empirical studies suggest that EFL students show a high level of divergence between the use of English for classroom oral communication and the use of English outside the classroom (Littlewood, 2007). In addition to the classroom, the scope for the use of English is limited outside the classroom; therefore, the students are likely to use their first language for daily interactions. In this context, this raises an important question regarding the extent to which classroom speaking practices are transferred to real-life English use. This issue is particularly evident among first-year students. In their early stage of higher learning, many of these students will be enrolled in foundation-level English classes, where their proficiency level ranges from low-intermediate (A2-B1) and their communicative confidence is low. In this transitional period, their affective variables, such as anxiety, fear of making errors, and communicative confidence may play a major role in impeding their willingness to communicate in English, especially in real-world contexts (MacIntyre et al., 1998). They may be highly involved in speaking tasks in class but simultaneously avoid using English outside of class.

While prior studies have examined the teaching of speaking in the classroom from the perspective of EFL settings, not many studies have attempted to examine the ways students use spoken English in various learning contexts, particularly by comparing the use of speaking in the classroom and out of the classroom. In addition, not many studies have attempted to consider the students' own perspectives to account for the prevalence of English speaking in some contexts more than others. In fact, researchers have called for more attention to students' use of language in real contexts to better evaluate the effectiveness of communicative language teaching (Benson, 2011).

While previous studies have extensively explored classroom-based speaking practices in EFL settings (e.g., Bygate, 2001; Nation & Newton, 2009; Goh & Burns, 2012), relatively limited attention has been paid to how instructional speaking practices connect with authentic English use beyond the classroom, particularly from students' perspectives in Asian EFL contexts (Lamb & Arisandy, 2020; Nguyen & Habók, 2023). Specifically, there is a need to bridge the gap between instructed classroom-based speaking and the use of English outside the classroom from the point of view of students themselves, especially first-year Vietnamese university students. To bridge this research gap, the present study aims to explore the ways in which first-year university students employ English for speaking purposes in classroom settings as well as in-class and out-of-class situations. The research aims to explore the ways in which English speaking takes place across different learning environments, as well as the factors that affect English-speaking in and out-of class situations. In line with the research aims, this study employed an explanatory sequential mixed-methods research design to explore English-speaking in EFL university settings. In this regard, the research was guided by the following research questions:

1. How do first-year university students report using English for speaking purposes inside the classroom during a preparatory English program?

2. How do first-year university students report using English outside the classroom in real-life communicative contexts?

3. What factors influence first-year university students' reported use of English-speaking practices outside the classroom?

2. Literature review

2.1 English Speaking in EFL University Contexts

English speaking is considered one of the key aspects of communicative competence in the teaching of second or foreign languages (Canale & Swain, 1980; Richards, 2008). In the context of higher education, the importance of speaking is that it allows the learner to take part actively in the interaction in the classroom, in academic discussions, etc. Speaking competence in EFL contexts involves not only linguistic accuracy but also the ability to communicate fluently and appropriately in meaningful contexts (Bygate, 1987; Richards, 2008).

In many Asian EFL contexts, including Vietnam, classroom interaction remains the primary source of English-speaking practice because opportunities for authentic communication outside the classroom are limited (Littlewood, 2007). As a result, university preparatory English programs often place considerable emphasis on classroom-based speaking activities designed to develop students' basic communicative competence (Hyland, 2006; Richards, 2008). Understanding how students engage in English-speaking practices within and beyond these instructional settings is therefore important for evaluating the effectiveness of EFL speaking instruction.

2.2 Classroom and Out-of-Class English Speaking

In EFL contexts, classroom interaction functions as the primary environment for English-speaking practice because opportunities for authentic communication outside the classroom remain limited (Littlewood, 2007; Benson, 2011). Classroom speaking activities, including teacher–student interaction, pair work, group discussions, and task-based interaction, provide important opportunities for learners to practice and develop spoken English skills (Richards, 2008). However, such interaction is often pedagogically structured and highly task-oriented, with learners responding to teacher prompts rather than engaging in spontaneous communication (Ellis, 2003; Littlewood, 2007). Although these classroom activities may support the development of linguistic competence, they do not necessarily facilitate the transfer of English-speaking practices to real-life communication. This suggests that classroom participation alone may not automatically lead to authentic communicative engagement in EFL contexts due to differing communicative purposes and environmental constraints. Previous studies have suggested that learners who actively participate in classroom-speaking activities may still avoid using English outside the classroom (Littlewood, 2007).

In contrast, out-of-class English speaking typically occurs in less formalized contexts, such as communication with friends, service encounters, or online interaction (Benson, 2011). Recent studies have also explored learners' willingness to communicate beyond the classroom through both human-human and technology-mediated interaction. For example, research has shown that interaction with intelligent personal assistants may increase learners' willingness to communicate outside formal classroom settings by reducing communication anxiety and providing accessible opportunities for English use (Tai, 2024). In many EFL settings, however, such opportunities remain relatively scarce. Benson (2011) argues that learners' out-of-class English use depends largely on both the availability of communicative opportunities and learners' willingness to seek them. As a result, English-speaking practices outside the classroom tend to occur far less frequently than classroom-based speaking activities. Taken together, the literature suggests a substantial discrepancy between classroom participation and authentic English use.

2.3 Factors Influencing English-speaking practices beyond the classroom

Recent studies have pointed to a variety of factors that play a significant role in influencing learners' willingness and ability to use English for speaking outside the classroom

(MacIntyre et al., 1998; Benson, 2011). Among these factors, affective factors have been extensively studied. Collectively, previous studies suggest that affective factors such as anxiety, fear of negative evaluation, and low confidence substantially constrain learners' willingness to communicate in EFL contexts (Horwitz, 1986). Recent studies have also shown that positive affective variables, such as foreign language enjoyment and teacher support, significantly influence learners' willingness to communicate in EFL contexts (Yang et al., 2024). These affective constraints might be compounded in out-of-class situations where learners are more vulnerable to negative social evaluation (Horwitz, 1986; MacIntyre et al., 1998).

The Willingness to Communicate (WTC) framework provides an important perspective for understanding why EFL learners may avoid speaking English outside the classroom despite possessing sufficient linguistic knowledge (MacIntyre et al., 1998). For EFL learners, low levels of willingness to communicate result in the reluctance to engage in English speaking, despite the presence of linguistic competence in the target language (MacIntyre et al., 1998). Similar findings have also been reported in Asian EFL contexts, where learners' communicative confidence and readiness to engage in English interaction is closely associated with confidence and perceived communicative competence (Yashima, 2002). In the Vietnamese EFL context, Nguyen and Vu (2024) similarly reported that learners' willingness to communicate was negatively influenced by affective barriers such as communication anxiety, fear of negative evaluation, and low self-confidence. Besides the role played by affective variables, the impact of contextual or environmental factors cannot be overlooked. For instance, the scarcity of English-speaking interactional partners, the preference to speak the first language, and the absence of communicative need all contribute to the reluctance to engage in real-life interaction in the target language (Littlewood, 2007; Benson, 2011). These factors, in aggregate, result in the reluctance to engage in English speaking outside the classroom (Littlewood, 2007; Benson, 2011).

According to the reviewed literature, the importance of speaking in EFL university education is emphasized, and the classroom is identified as the main setting in which English-speaking practice occurs. The reviewed research has also identified various affective and contextual factors affecting learners' English-speaking practice outside the classroom. However, there are still gaps in the research in this area.

Firstly, despite extensive research on classroom-based speaking instruction in EFL contexts (Richards, 2008; Littlewood, 2007), relatively limited attention has been paid to the discrepancy between classroom participation and real-life English-speaking practices, particularly among first-year university students in Vietnam. Secondly, relatively limited research has focused specifically on first-year university learners enrolled in preparatory English programs, whose communicative confidence and speaking practices may differ from those of more advanced learners due to affective factors such as anxiety and willingness to communicate (MacIntyre et al., 1998). Thirdly, previous studies in this area have often relied primarily on either quantitative or qualitative approaches, while fewer studies have adopted mixed-methods designs to examine English-speaking practices across classroom and out-of-class contexts (Benson, 2011; Littlewood, 2007). In order to fill the gaps in the research, the study employed a mixed-methods research approach to explore the English-speaking practice of first-year university learners in the classroom and outside the classroom, as well as the factors affecting learners' English-speaking practice outside the classroom. The study aims to contribute to the theoretical discussion on how English-speaking practice in the classroom can be promoted to learners to be used outside the classroom.

3. Methodology

3.1 Research design

This study followed an explanatory sequential mixed-methods design, in which quantitative data were collected and analyzed first, followed by the collection and analysis of qualitative data (Creswell & Plano Clark, 2018). The use of a mixed-methods approach was considered appropriate because it enabled the researcher to identify patterns of English-speaking practices across classroom and real-life communicative contexts while also exploring the underlying factors influencing students' English use from the learners' perspectives.

More specifically, the quantitative phase focused on identifying patterns of English-speaking practices inside and outside the classroom, whereas the qualitative phase explored the reasons underlying students' use or non-use of English in real-life communicative situations. The integration of quantitative and qualitative findings provided a more comprehensive understanding of English-speaking practices among first-year university students.

To ensure theoretical grounding, the study was informed by theories of communicative language use and second language communication behavior, particularly Communicative Competence Theory (Canale & Swain, 1980) and the Willingness to Communicate framework (MacIntyre et al., 1998). These theoretical perspectives informed the conceptualization of English-speaking practices as well as the interpretation of the findings.

3.2 Theoretical Framework

The research has been informed by Communicative Competence Theory, as well as the Willingness to Communicate (WTC) model, which provide a unifying framework to guide the research on the phenomenon of English-speaking practices from the perspective of English as a Foreign Language (EFL) context. From the perspective of communicative competence theory, speaking has been conceptualized as "the ability to convey linguistically accurate, fluent, and appropriate language in meaningful contexts, especially in the classroom" (Canale & Swain, 1980; Richards, 2008).

To expand the scope of the study to the wider phenomenon of English-speaking practices beyond the classroom, the WTC model is applied, which posits that language use is shaped by situational factors such as context and the people involved, as well as individual factors such as confidence or anxiety, in the language user (MacIntyre et al., 1998). The synthesis of the two theoretical frameworks provides the potential to offer an explanation of the reason why, despite the linguistic competence, the learner does not engage in real-life communicative situations. These theoretical perspectives informed the interpretation of students' reported speaking practices and the affective and contextual factors associated with English use beyond the classroom.

3.3 Research context and participants

The research was conducted in a private university in Vietnam. English is considered a foreign language in Vietnam. The first-year undergraduate students in the university are expected to take a course in English before they are allowed to specialize in the actual field of study. The course is expected to help the students learn the basics in English, with a focus on speaking. The total number of students in the research was 50. The students in the research were all enrolled in the English course at the time the research was conducted. The level of the students' English was at the A2-B1 level on the Common European Framework of Reference for Language Levels. The research was on a volunteer basis, and all the students were made aware of the confidentiality of the research. The research participants were chosen using a

method of convenience sampling since they were accessible to the researcher during the preparatory English program. Even though such a method of sampling makes the results non-generalizable, it is considered appropriate for exploratory research.

3.4 Data collection instruments

3.4.1 Quantitative data collection methods, in the form of a structured questionnaire, were used to measure the extent of students' use of English in their classrooms and out-of-class activities. The questionnaire had two parts, A and B. In part A of the questionnaire, the background information of the participants, such as their academic background and their level of proficiency in English, was collected. In part B of the questionnaire, the extent of students' use of English in their classrooms was measured by asking them to report their use of English in situations such as answering teachers' questions, participating in pair/group discussions, their use of English in real-life situations outside the school context, etc.

The extent of students' use of English, as reported by the participants of the study, in part B of the questionnaire, is measured by a five- point Likert scale ranging from never to very often. Items in the questionnaire are supported by literature regarding EFL speaking and willingness to communicate. The questionnaire was based on prior research on EFL speaking behaviors and willingness to communicate, as reported by researchers such as MacIntyre et al. (1998) and Benson (2011). To establish content validity, the questionnaire was validated by two EFL lecturers with considerable experience. The pilot study was carried out with a small group of students, consisting of 10 students, to test its reliability and make minor modifications if necessary. The internal consistency of the questionnaire was satisfactory, with a Cronbach's alpha coefficient of 0.82.

3.4.2 Semi-structured interviews

In addition to the quantitative questionnaire, semi-structured interviews were conducted to explore students' perceptions of English use outside the classroom in greater depth. A total of 10 volunteer participants participated in follow-up interviews after the quantitative phase. The interviews focused on students' experiences, attitudes, and perceived difficulties related to using English in real-life communicative situations.

The interviews lasted approximately 15–20 minutes and were conducted in Vietnamese to allow participants to express their perspectives more comfortably and accurately. With participants' consent, the interviews were audio-recorded and later transcribed for thematic analysis. The use of follow-up interviews in explanatory sequential mixed-methods research helped provide deeper explanations for the quantitative findings (Creswell & Plano Clark, 2018). In addition, the number of interview participants was considered appropriate for exploratory qualitative inquiry and thematic analysis, where relatively small samples may still provide sufficient thematic depth and saturation (Braun & Clarke, 2006; Guest et al., 2006).

3.5 Data collection procedure

The data collection was done in the middle of the English preparatory program. This ensured a high rate of return because it was administered in class. It took the participants about 20 minutes to answer the questionnaire. After analyzing the quantitative data, the semi-structured interviews were conducted. This ensured that the qualitative part explained the quantitative part.

3.6 Data analysis

Descriptive statistics, including frequencies, percentages, means, and standard deviations, were used to analyze quantitative data and identify patterns of English-speaking practices across contexts. In addition, a Wilcoxon signed-rank test was conducted to compare students' reported English-speaking frequency inside and outside the classroom, as the data involved paired ordinal Likert-scale responses from the same participants. In terms of qualitative data analysis, thematic analysis was used following the six-phase procedure suggested by Braun and Clarke (2006), which involved familiarization with the data, generating codes, searching for themes, reviewing themes, defining and naming themes, and producing the report. This helped to identify major patterns related to affective and contextual issues in the students' use of English outside the classroom setting. Data collection and analysis continued until thematic saturation was reached, that is, when no substantially new themes or patterns emerged from the interview data (Guest et al., 2006). Recurrent ideas became increasingly repetitive across participants, suggesting sufficient thematic coverage for the purposes of the study. To enhance trustworthiness, the researchers discussed and refined the coding categories collaboratively throughout the analysis process.

3.7 Ethical Considerations

Ethical consideration was strictly adhered to in the study. Participants were made aware of the study's objectives, as well as their right to withdraw at any time with no penalty. Informed consent was obtained before data collection, with confidentiality of the collected data being ensured by anonymizing the information collected. Data collection was limited to research purposes only. All participants provided informed consent prior to participation, and no personal identifying information was collected to ensure anonymity.

4. Findings

4.1. Questionnaire findings

4.1.1 English-Speaking Use inside the Classroom

The results of the questionnaire indicate that English speaking was frequently used inside the classroom during the English preparatory program. Overall, students reported high levels of engagement in English-speaking activities inside the classroom, especially when these activities were teacher-initiated.

A majority of participants (78%) reported frequently using English to answer teachers' questions. The activity was found to be used most frequently compared to all other speaking activities, with a mean score of M = 3.96 (SD = 0.61) on a five-point Likert scale. In parallel, it was found that 72% of students (n = 36) reported that they frequently took part in pair or group discussions held in English.

In contrast, it was found that speaking activities that required higher spontaneity were used less frequently. Only 34% of participants (n = 17) reported that they frequently volunteered to give their opinions without being prompted by teachers, whereas 46% (n = 23) reported that they seldom did so. The mean score was M = 2.91 (SD = 0.83).

These findings reveal that English speaking in the classroom was primarily facilitated by the teacher and was task-based, as students relied on instructional cues to engage in English speaking. Although English speaking was highly facilitated by opportunities provided by the classroom, these opportunities were primarily task-based and embedded in instructional contexts rather than students' spontaneous English speaking.

Classroom English-speaking activities	Never (%)	Rarely (%)	Sometimes (%)	Often (%)	Very often (%)	Mean	SD
Responding to teachers' questions	2 (4%)	4 (8%)	5 (10%)	21 (42%)	18 (36%)	3.96	0.61
Participating in pair/group discussions	3 (6%)	6 (12%)	5 (10%)	20 (40%)	16 (32%)	3.74	0.67
Giving prepared oral responses	4 (8%)	7 (14%)	10 (20%)	18 (36%)	11 (22%)	3.50	0.79
Volunteering opinions without prompts	8 (16%)	15 (30%)	10 (20%)	12 (24%)	5 (10%)	2.91	0.83

Table 1

Frequency of English-Speaking Use inside the Classroom (n = 50)

As illustrated in Table 1, English speaking inside the classroom was most often engaged in during teacher-initiated activities. Responding to teacher-posed questions was the most common form of English speaking, achieving the highest mean score (M = 3.96, SD = 0.61), while participating in pair or group discussions came second (M = 3.74, SD = 0.67). English speaking engaged in for the purpose of self-initiating, such as volunteering opinions without any prompts, was reported the least (M = 2.91, SD = 0.83).

4.1.2 English-Speaking Use outside class in Real-Life communicative Contexts

In contrast to the school context, the use of English outside the school was found to be limited. The data collected by the questionnaire show that there was a considerable decrease in the rate of English use when the contexts of real-life English-speaking activities were considered.

In the outside class context, only 18% of the participants (n = 9) reported that they used English frequently or very frequently, whereas 62% of the participants (n = 31) reported that they used English rarely or not at all for speaking activities in daily life. The overall mean score for the use of English outside the school for speaking activities was M = 2.14 (SD = 0.71), which was significantly lower than the score for English-speaking activities in the school context.

However, a closer examination of the data indicated that 70% of the students (n = 35) used English infrequently when interacting with their peers, including those who were simultaneously taking English courses. Additionally, 76% of the students (n = 38) stated that they used English almost never when interacting in service encounters, such as ordering food, shopping, or seeking information. The use of English in online communication was slightly higher but still limited, with 42% (n = 21) of the students stating that they used English occasionally.

The above data suggest that there was a significant gap in the use of English in the classroom and in out-of-class contexts. Although the students used English frequently in the

classroom, they used English minimally in real-life communicative contexts. A Wilcoxon signed-rank test revealed a statistically significant difference between students' reported English-speaking frequency inside and outside the classroom, with classroom speaking reported more frequently, $Z = -5.42$, $p < .001$, $r = .77$, indicating a large effect size.

Out-of-class English-speaking contexts	Never (%)	Rarely (%)	Sometimes (%)	Often (%)	Very often (%)	Mean	SD
Communicating with friends in English	15 (30%)	20 (40%)	8 (16%)	5 (10%)	2 (4%)	2.18	0.88
Using English in service encounters (e.g., shopping, ordering food)	18 (36%)	20 (40%)	7 (14%)	4 (8%)	1 (2%)	2.00	0.82
Using English in everyday interactions outside class	17 (34%)	21 (42%)	8 (16%)	3 (6%)	1 (2%)	2.00	0.80
Using English in online communication	10 (20%)	14 (28%)	11 (22%)	10 (20%)	5 (10%)	2.72	1.12

Table 2

Frequency of English-Speaking Use outside class (n = 50)

As shown in Table 2, English use outside the school environment was found to be generally low in most real-life situations. The lowest mean scores were found in service encounters and daily interactions, which had a mean of 2.00 each, implying that most students made little to no use of English in these situations. Although English use in online communication seemed to be a bit more frequent, with a mean of 2.72 and a standard deviation of 1.12, it is still low compared to English use in speaking activities in the classroom. In conclusion, there is a big gap between English-speaking use in the classroom and English use outside the school environment.

4.2 Qualitative Findings from semi-structured interviews

A total of 10 out of the 50 participated in the semi-structured interviews. The answers were analyzed using thematic analysis to investigate the perceptions of the use of English outside the classroom and the quantitative patterns. Two major themes were identified from the answers: affective factors and contextual/environmental factors.

4.2.1 Affective Factors Influencing English-Speaking Use

The affective factors proved to be the most important factor in explaining the students' minimal usage of English outside of academic settings. Out of the ten students, seven students pointed out that their lack of confidence in speaking English was the major factor in not using English in everyday life. Some of the students had concerns about their English pronunciation, vocabulary, and grammar, which made them reluctant to speak English unless they had to. One student said: *"I am not confident about my pronunciation, so I usually avoid speaking English outside the classroom."* (Student 3)

Another student similarly noted:

"I worry that I might use wrong words or grammar, so I feel safer not speaking English." (Student 7)

Moreover, six of the ten students cited fear of errors or negative evaluation as a significant factor in their response to barriers. These students saw the level of stress in communication in the real world as greater than in the classroom, where making errors is acceptable. One of the students explained:

"In class, making mistakes is normal, but outside the class I am afraid people will judge my English." (Student 1)

Another student highlighted the anxiety associated with speaking to unfamiliar interlocutors:

"When I speak English with strangers, I feel very nervous because I don't want them to think my English is bad." (Student 9)

These responses indicate that affective constraints—particularly low confidence and fear of negative evaluation—played a crucial role in shaping students' English-speaking behavior outside school, despite their active participation in classroom speaking activities.

4.2.2 Contextual and Environmental Factors

In addition to affective factors, students also identified contextual factors that constrained their opportunity to use English outside of class. Of the 10 students, eight students identified that they had limited opportunity to use English in daily life because the majority of interactions were conducted in their native language. Some of the students emphasized that English was not required outside of class, which affected their motivation to initiate English-speaking interactions. One student commented:

"In daily life, everyone speaks Vietnamese, so there are not many chances to use English." (Student 4)

Another student explained:

"Outside school, English is not really necessary, so I don't think about using it." (Student 10)

Moreover, five of the ten students identified the lack of English-speaking interlocutors as an important barrier. Although the students were willing to practice their English skills, they encountered difficulties in locating interlocutors who were willing to communicate in English.One participant noted:

"I want to practice English, but my friends prefer speaking Vietnamese." (Student 6)

Another student echoed this concern:

"It is hard to find someone to talk to in English, so I usually use my first language." (Student 8)

Together, these contextual and environmental factors reinforced the gap identified in the quantitative findings, constraining students' English-speaking use beyond the classroom.

5. Discussion

This study is concerned with exploring the students' English-speaking practices in the classroom and in real-life situations in an EFL context, as well as the factors that affect students' engagement in English speaking activities outside the classroom. The findings show that there is a large gap between students' English speaking in the classroom and in real-life situations, which can be explained in terms of communicative competence and WTC.

5.1 Classroom English Speaking as Instructed Communicative Practice

Moreover, the findings of the questionnaire show that English-speaking frequently occurred in classroom settings, particularly in activities initiated by teachers, such as answering teachers' questions and participating in pair or group discussions. This finding suggests that classroom speaking remains largely pedagogically controlled, limiting the development of spontaneous communicative competence, which aligns with Littlewood's (2007) distinction between form-focused and meaning-focused interaction. The slightly higher mean scores in these activities suggest that the English preparatory program provides students with opportunities to practice English-speaking in the classroom.

The low incidence of self-initiated oral contributions, such as volunteered opinions may imply that English speaking in the classroom was still largely controlled. From the point of view of communicative competence (Canale & Swain, 1980; Richards, 2008) these classroom practices may promote the development of linguistic accuracy and fluency but may not necessarily facilitate spontaneous communicative use in authentic contexts. Thus, the findings imply that while students were engaged in English speaking activities, these activities were still largely in the context of instruction, not communicative need.

5.2 Limited Transfer of Classroom Speaking to Real-Life communicative contexts

A key finding of the study is the markedly low frequency of English-speaking use outside school. The majority of students reported very little or no use of English in out-of-class situations, such as interactions with peers or service encounters. This finding supports the claims made in earlier research that classroom ability does not necessarily equate to the use of the target language in other situations (Littlewood, 2007).

The slight increase in the use of English in online communication may be an indicator of the potential of these online contexts to be relatively safe avenues for English-speaking activities. However, the overall use of out-of-class English language use is still restricted, which aligns with the notion that English language use is often perceived by EFL learners as an academic subject. This aligns with Benson's (2011) notion that out-of-class language use in the context of EFL settings is heavily dependent on the opportunity and the agency of the learners.

5.3 Affective Constraints and Willingness to Communicate

Qualitative findings provide substantial insights into the factors that prevent students from using English outside of the classroom. Among the ten students, low self-confidence and fear of making mistakes dominated the affective factors that prevent students from using English outside of the classroom, which is consistent with the literature of FLA that indicates that fear of negative evaluation is one of the most important factors that prevent students from using English, according to Horwitz (1986). Similar patterns have been identified in Asian EFL classrooms, where students' willingness to communicate is strongly influenced by confidence, classroom climate, and fear of negative evaluation (Peng & Woodrow, 2010).

Interpreted in the light of the WTC framework proposed by MacIntyre et al. (1998), the results suggest that the willingness to use English outside the classroom is not limited by the lack of linguistic knowledge, but rather by other factors. For instance, the students who were actively using English in the classroom were still reluctant to use it outside the classroom due to the risk of communication. This is in support of the contention that linguistic knowledge is not enough to account for the use of the target language, especially in EFL settings.

5.4 Contextual Constraints and Lack of Communicative Necessity

Apart from affective factors, contextual and environmental factors also limited students' English-speaking practices. The major part of interviewed students emphasized that most interactions were based on the first language and that there was no need to use English outside the school environment. This result corresponds to previous research that showed that lack of exposure and absence of communicative need reduce students' motivation to use the target language outside the classroom (Littlewood, 2007; Benson, 2011).

The difficulty in finding an English-speaking interlocutor again illustrates the ways in which the environmental factors work in tandem with the affective factors to create an unwillingness to communicate in English. In the WTC framework, the role of the contextual factors is to reduce the learner's situational willingness to communicate, despite the learner's underlying motivation to improve his/her speaking skills in English. The interplay between the affective and contextual factors explains the continued gap between the learner's use of English in the classroom and in the real world, as seen in the results of this study.

5.5 Pedagogical Implications

The results of this research also reveal several implications for English language teaching pedagogy in preparatory English programs offered in EFL university contexts. Firstly, while speaking activities in the classroom are undoubtedly important, more attention needs to be devoted to overcoming affective factors by creating a speaking environment that encourages risk-taking and self-initiated speaking. Secondly, it may be necessary to take English language teaching beyond the confines of the classroom by designing speaking tasks that involve out-of-class speaking.

Finally, promoting students' understanding that English is not just an academic subject but also a viable means of communication may enhance their interest in communicating beyond the classroom. Such changes in teaching methods may help bridge the gap between instructed language use and communicative language use.

5.6 Summary

In summary, the findings highlight a substantial limited correspondence between instructional speaking activities and spontaneous English interaction which is shaped by the interaction of instructional, affective, and contextual factors. While the classroom provides learners with the opportunity to practice speaking in English frequently, it is important to note that the opportunity to practice speaking in the classroom does not necessarily equate to the real-life setting.

5.7. Limitations

In spite of the positive contributions of the study, several limitations need to be pointed out.

Firstly, this study had a small sample size of 50 participants from a private university in Vietnam. This may limit the generalizability of the findings to broader EFL contexts. Secondly, the present study is based on self-report measures of the participants. The responses gathered by the survey technique are prone to the influences of recall and social desirability biases. Therefore, one cannot be sure that they reflect fully the students' actual behavior of using English to communicate. Future research should triangulate self-reported questionnaire and interview data with more objective sources of evidence, such as classroom observations, speaking performance assessments, audio/video recordings of speaking tasks, and teacher evaluations.

Thirdly, although the study had a mixed-methods design, the qualitative part of the study had a small sample size of 10 participants. This might not have been representative of the entire range of the participants' experiences. In addition, the study focused more on the frequency of the participants' English-speaking behavior rather than the effectiveness of the communication. This is another limitation of the study.

Lastly, this study is a snapshot of the participants' behavior and cannot account for changes in the participants' behavior over time. Future studies might employ longitudinal designs to assess the development of the participants' English-speaking behavior. Despite these limitations, the study provides important insights into the gap between classroom-based and real-life English-speaking practices in EFL contexts.

6. Conclusion

This study examined the speaking practices of first-year university students both inside the classroom and in real-life situations in the context of an English as a Foreign Language (EFL) classroom. The study's findings reveal a wide gap in the level of participation in speaking practices inside the classroom and the limited use of such practices outside the classroom. Despite the opportunities for speaking practice inside the classroom, such practice may not easily extend to authentic communicative contexts. The study's findings also reveal the importance of affective factors in the use of English outside the classroom. The low level of confidence, the fear of making mistakes, and the anxiety stemming from negative evaluation all served to limit the students' willingness to communicate. The lack of opportunities and the lack of communicative necessity also limited the students' use of English outside the classroom.

From the perspective of language teaching, the study's findings reveal the importance of moving beyond the classroom-bound speaking practice to more authentic, meaningful, and confidence-building speaking practice. The study's findings also reveal the importance of language teaching going beyond the development of students' linguistic knowledge to the development of their willingness and readiness to communicate in real-life situations.

The study's findings also have important implications for the development of students' readiness to communicate in the global academic or professional community, where the ability to communicate orally plays a crucial role. Future studies on the speaking practices of students need to be longitudinal studies to reveal the development of students' speaking practices over time.

#18 Exploring University Students' Use of AI Tools in Academic Writing at HUFLIT

Phan Ngoc Phuong Vy[1]

Abstract

The past few years have witnessed the rapid emergence of generative artificial intelligence (AI) tools which have significantly reshaped the academic writing processes in higher education. There has been an increasing tendency among the undergraduates to utilise AI-powered platforms to support multiple stages of academic writing, including brainstorming, initial drafting and revision processes. This study is aimed to explore how university students describe their experiences of employing AI-driven tools in their academic writing works and their attitudes towards AI's position in reconstructing their writing practices. Adopting a qualitative research design, this study relied on semi-structured interviews conducted with first-year students at HUFLIT who frequently integrate AI tools in their academic writing tasks. The collected data underwent thematic analysis to identify recurring patterns that reflect their experiences and interpretation for their engagement with AI in writing skills. The findings reveal that the participants perceived AI as a form of cognitive scaffolding which supported idea generation, language refinement and structural organisation throughout their academic writing tasks. Concurrently, the students expressed concerns about the over-reliance on AI tools, the difficulties in identifying authorship and the academic integrity. Lastly, the results suggest that students had mixed views of AI's impacts on their future writing development while attempting to balance between efficiency brought by AI and their true skill development. This study expects to contribute profound understanding of responsible AI integration and relevant pedagogical approaches to academic writing skills in the era of generative AI.

***Keywords*:** generative AI, academic writing, EFL, university students, qualitative study

1. Introduction

The widespread expansion of generative AI tools, such as ChatGPT, has substantially transformed academic writing practices in higher education, influencing the way learners brainstorm ideas, organise texts and refine their language (Zhao et al., 2024). Recent studies on generative AI highlight its increasing integration into student academic wiring class, suggesting that these technologies are not only used for surface-level editing, but also function as cognitive assistance in more complex writing processes (Sanz-Tejeda et al., 2026). Besides, syntheses of research in AI-integrated writing suggest that students employed these tools to enhance coherence, lexical quality and textual organisation; at the same time, these researchers also identified a number of potential drawbacks, including growing dependence, ethical concerns and deterioration in metacognitive development (Chanpradit, 2025; Sanz-Tejeda et al., 2026).

In addition to the reported efficiency in improving writing performance, students also hold varied views towards AI tools. Particularly, qualitative studies exploring students' perspectives on AI tools indicate that AI is expected to function diverse pedagogical roles, from a drafting assistant to a virtual tutor facilitating different phases of the writing process (Kim et al., 2024). Such findings strengthen AI's potential in supporting students' writing activities

[1] *MA, Faculty of Foreign Languages (FFL), HUFLIT, Ho Chi Minh City, Vietnam; Email: vypnp@huflit.edu.vn*

while also revealing its challenges in applying AI academic tasks in general. Although a growing literature of research has explored students' patterns of AI usage and their general perceptions of these technologies, many of these current studies are largely constructed on survey-based and quantitative methodologies, thereby paying little attention to the depth and complexity of students' lived experiences with AI integration in their academic writing phases. Besides, this limitation in methodologies also resulted in limited insight into students' interpretation of AI's role in shaping their academic writing skills, particularly in Vietnam where national policies have increasingly emphasised the importance of transforming English education from a traditionally foreign-language system into a second-language oriented framework.

Furthermore, most existing studies are situated within general higher education or non-EFL environments, resulting in a significant research gap in understanding about how learners in EFL university context use AI and interpret its role in academic writing. To address this gap, this study adopts a qualitative interview design with university students at the Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT) to answer two research questions:

1. How do university students at HUFLIT describe their experiences of using AI tools in academic writing?

2. How do university students at HUFLIT make sense of the role of AI tools in shaping their academic writing practices?

By focusing on students' perspectives in a Vietnamese EFL university context, this research aims to deepen understanding of AI-mediated academic writing activities and offer pedagogical approaches that balance technological benefits and ethical considerations in EFL higher education.

2. Literature Review

2.1. AI as Cognitive and Linguistic Scaffolding in Academic Writing

The increasing growth of generative AI tools has substantially transformed academic writing practice within higher education institutions. In particular, recent studies argue that AI-based platforms, such as ChaGPT, operate not merely as editing tools, but as cognitive assistance that facilitates idea generation, organisation, drafting and iterative revision (Kasneci et al., 2023; Dwivedi et al., 2023; Zhai, 2023). Unlike earlier grammar-check softwares, generative AI tools are capable of generating extended and coherent responses, which allows learners to interactively engage in the drafting and language refinement processes (Rudolph et al., 2023). As a result, these tools are widely recognised as forms of technological scaffolding that mediate cognitive processes during complex writing tasks (Farrokhnia et al., 2023).

In fact, the writing process includes several repeated phases, such as idea planning, composing and draft reviewing (Flower & Hayes, 1981). Generative AI tools can be employed to facilitate these stages by providing prompts, suggesting structures and improving sentence formulation (Yan, 2023; Wang et al., 2024). Such support is consistent with earlier studies on the digital writing environment, which suggest that technology can influence not only the textual output produced by writers but also the cognitive strategies writers employ when composing (Warschauer, 2010). Therefore, AI-assisted writing can be seen as a higher stage of computer-mediated composition, where technology supports both language correction and complex idea development.

The scaffolding function above may be especially important in EFL contexts, where the act of writing in a foreign language demands greater cognitive load due to restricted lexical resources, grammatical uncertainty and unfamiliar disciplinary norms (Hyland, 2019). Within such settings, AI-generated feedback can reduce linguistic burden and support the development of fluency in writing (Alhusaiyan, 2024; Jacob et al., 2024). Moreover, a recent empirical study show that students perceive AI as an integrated writing partner, rather than a tool offering only surface support such as idea generation, organization and iterative revision (Kim et al., 2024; Woo et al., 2026). While Kasneci et al. (2023) emphasise the pedagogical benefit of large language models in fostering learner autonomy, Dwivedi et al. (2023) indicate that the effective impact of AI on the learning process depends on how students integrate these tools into their writing practices. In summary, these studies suggest that AI has the capacity to improve both academic writing performance and cognitive development throughout the whole writing process itself. However, to capture the nature of this transformation, it is a must to explore how students describe their experiences with AI and interpret its role in enhancing writing competence.

2.2. Students' Conflicting Feelings about Using AI in Writing

Despite the widespread adoption of these AI tools, students' perceptions of their roles are often complex and sometimes ambivalent. In particular, a number of empirical studies report that many learners view generative AI as beneficial tools that improve clarity, lexical diversity and structural coherence (Baidoo-Anu & Ansah, 2023; Chan & Hu, 2023). Specifically, learners commonly explain they use AI to overcome writer's block, outline structures and paraphrase ideas, especially in ESL or EFL contexts. From this perspective, AI is frequently conceptualised as a supportive assistant that enhances writing efficiency and learner confidence.

Simultaneously, current research has raised concerns regarding over-reliance, academic integrity and authenticity of ownership (Cotton et al., 2023; Baidoo-Anu & Ansah, 2023). In particular, Cotton et al. (2023) argue that the extended accessibility of generative AI tools disrupts the traditional understanding of originality, and thereby creating challenges for educational organisations to maintain academic integrity. Consistent with the aforementioned studies, Chan and Hu (2023) also report that students appreciate the benefits of AI yet remain uncertain about its ethical limits. Similarly, within EFL settings, students indicate that ChatGPT – a common AI-based tool – contributes to improved writing performance, reduced anxiety and greater confidence; however, they also express concerns about excessive dependence and ownership (Teng, 2024; Barzanji & Alsofyani, 2026). This implies that students do not use AI in a simple and practical way. In other words, students question whether AI supports their learning or threatens the originality of their writing. Such complicated perceptions highlight the need to understand how learners interpret the adoption of these mediating technologies in their writing practices, rather than simply focusing merely on how frequently they use these tools.

2.3. Shifting the Focus from Outcomes to Student Perspectives

Although the interest in AI-assisted writing practice is increasingly growing, most previous studies concentrate on student performance, institutional policies and university reactions, rather than students' personal experience. A number of investigations address the potential transformation that educational systems may undergo and suggest future strategies in the era of generative AI (Dwivedi et al., 2023; Kasneci et al., 2023). In the meantime, others concentrate on academic integrity and regulation (Cotton et al., 2023). While these

contributions are valuable to understand policies and institutional settings, they pay less attention to how learners actually experience and integrate AI in their writing practices.

A number of survey-based research seem useful when identifying students' general attitudes towards AI-mediated writing processes (Baidoo-Anu & Ansah, 2023; Chan & Hu, 2023). However, these quantitative-designed studies often view these attitudes as numbers and fixed variables, rather than as emotions and experiences that may change and develop over time. In fact, academic writing activities which are socially shaped allow students to develop and express their understanding. As a result, if AI is used for initial drafting and revision, it may affect how students perceive authorship and their responsibilities. To fully understand this shift, qualitative research is necessary to explore students' detailed reflections on their experiences with AI.

2.4. AI Use in EFL Higher Education and the Need for Context-Sensitive Inquiry

The need for qualitative research becomes even stronger in EFL higher educational contexts. Academic writing in the EFL context is actually challenging due to linguistic limitations and academic standards (Hyland, 2019). In such cases, AI may function both as a tool to increase productivity and a linguistic support that influences their confidence and independence as writers. Although Kasneci et al. (2023) emphasise the potential of AI to support multilingual learners, and Dwivedi et al. (2023) highlight the importance of context-awareness when engaging AI in education, qualitative research examining students' experiences on AI-assisted writing in the EFL university settings remains limited.

2.5. Research Gap

In summary, existing studies suggest that generative AI-based tools in academic writing can serve as a form of cognitive support (Kasneci et al., 2023; Dwivedi et al., 2023) that students hold mixed views towards its use (Baidoo-Anu & Ansah, 2023; Chan & Hu, 2023); concurrently, these research shows that concerns about ethics and institutional policies are increasing (Cotton et al., 2023). Despite this fact, qualitative research exploring university EFL students' experiences and interpretations of AI's role in their academic writing mastery remains limited. Therefore, to address this gap, this study aims to investigate how students describe their engagement with AI in academic writing tasks and how they understand its impact on their academic writing development.

2.6. Theoretical Framework

This study is grounded in sociocultural theory (SCT), which views learning as a process that develops through social interactions with cultural tools within a particular environment (Vygotsky, 1980). From this viewpoint, cognitive development arises through interactions with mediational resources such as language, technologies and social relationships, rather than occurring solely within the individual's mind. In educational settings, such supports play a significant role in shaping the way learners engage with tasks, build knowledge and develop new competencies.

A key concept in SCT is mediation referring to the way how human cognition is shaped and supported by symbolic tools and cultural artifacts (Thorne & Lantolf, 2006). In second language acquisition, mediation commonly occurs through interactions with teachers, peers and instructional materials that guide and influence learners' performance. As digital technologies are increasingly present in higher education, they can function as mediational tools that shape the learning processes. Therefore, in the mastery of academic writing skills,

generative AI tools may serve as an effective support in generating ideas, organising arguments and refining language use.

Closely linked to mediation is the concept of the Zone of Proximal Development (ZPD), which mentions the gap between what learners can independently achieve and what they can accomplish with guidance and assistance (Vygotsky, 1980). Traditionally, such support within the ZPD has been offered by more knowledgeable individuals; nevertheless, these modern digital technologies are able to provide forms of assistance that is similar to guided support. As a result, suggestions, feedback and prompts created by AI-based tools may enable students to complete writing tasks that exceed their current linguistic or cognitive abilities.

Based on Vygotsky's SCT, another key concept is scaffolding built by Wood, Bruner, and Ross (1976), which describes temporary support provided to learners when they are engaged in tasks beyond their current capacities. In particular, within the setting of academic writing, AI tools may serve as scaffolding by helping students organise ideas, improve sentence formation and revise drafts. However, SCT highlights that tools do not automatically determine learning outcomes. Instead, their influence depends on how learners adopt and integrate them into their learning practices (Thorne & Lantolf, 2006). Guided by this perspective, this study explores how university students at HUFLIT describe their experience with AI tools and how these technological tools shape their academic writing practices.

3. Methodology

3.1. Research Design

This study employs a qualitative design to investigate university students' experiences with AI-powered tools in academic writing, because the qualitative approach is particularly appropriate for fully understanding how individuals interpret and make sense of their experiences within a social or educational context (Creswell & Poth, 2018). Semi-structured interviews were adopted to collect data, as this approach allows the researcher to obtain detailed description of participants while enabling flexibility to prompt ideas emerging from the interviews (Kvale & Brinkmann, 2015).

3.2. Participants

The sample consisted of 18 first-year university students majoring in English at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). Participants were recruited using a purposive sample, which merely choose those individuals who have relevant experiences to the phenomenon being studied (Patton, 2014). First-year undergraduate students were selected, because they are in the early stages of developing academic writing competency and are increasingly exposed to AI learning tools. The students were first recruited on a voluntary basis, and those who reported having used AI tools for learning and writing activities before would be invited to participate in semi-structured interviews. The sample size was determined according to the principle of data saturation, which occurs when no new themes or meaningful patterns emerge (Guest et al., 2006). Although the participants were first-year undergraduate students, they had completed several months of university study and academic writing practice prior to the interviews, enabling the study to capture emerging shifts in their use of AI tools and their engagement with AI-assisted writing.

3.3. Data Collection and Analysis

This interview protocol examined participants' motivations for AI usage, the particular phases in which these technologies are utilised, students' interactions with AI-generated

content, the initial transition in their behaviours and their reflections on authorship, responsibility and skill development.

The data were analysed using the thematic analysis approach proposed by Braun and Clarke (2006). The analysis involved several stages, namely familiarisation with the data, generalisation of initial codes, identification of recurring patterns and development of broader themes. This process allowed the author to identify the key themes reflecting student experiences with AI tools and their interpretation of AI tools' roles in their academic writing practices.

3.4. Ethical Considerations

Ethical considerations were carefully addressed throughout the research process. Participation was voluntary, and all students were informed about the purpose of the study before the interviews. All their responses were kept confidential and used only for the research purpose. To ensure anonymity, all participants were addressed as P1, P2, P3… during the analysis and reporting.

3.5. Theme Emergence and Data Saturation

Initial patterns appeared during the first few interviews, in which participants consistently described AI as a helpful tool that supports idea development and language refinement. As the interviews continued, more detailed patterns became evident, especially a shift from early dependence on AI-generated content to a more strategic and selective use. Data saturation was reached between Participants 12 and 15, as no new significant themes were identified after this stage. The subsequent three interviews were conducted to confirm the stability and comprehensiveness of the thematic framework, with patterns related to writing practices, AI use, and ethical issues.

4. Results

The thematic analysis of the interview data from 18 participants revealed four major themes that reflect students' experiences with AI tools in academic writing. Responses showed a high degree of consistency across participants, indicating similar patterns emerged among participants.

4.1. Theme 1: AI as a Multifaceted Writing Assistant

Across the dataset, all participants consistently conceptualised AI as a supportive "assistant" that facilitates linguistic and technical issues of writing practices, rather than substitutes human cognition. These students refer to AI as a multifaceted writing assistant that is effectively engaged in various stages of the writing process.

At the initial stage of writing, all participants reported utilising AI for brainstorming and outlining, especially to handle "writer's block" (P2) and build an initial structure. For example, Participant 2 depicted AI tools as "incredibly helpful for outlining, checking grammar, and refining vocabulary" while Participant 12 explained that they heavily relied on AI because they "found it difficult to create a clear outline and use formal academic language."

In the later stages of the writing process, AI was widely employed to proofread and refine language. In addition, participants reported relying on AI-based tools to enhance grammatical accuracy and strengthen the academic tone of their writing. In short, according to these findings, AI provides ongoing support, and thereby proves to be effective in both idea generation and language refinement.

4.2. Theme 2: Negotiating Dependence and Critical Engagement

As can be inferred from the dataset, students' use of AI showed a clear development over time. While early use of AI was characterised by a level of dependence, their later practices reflected a more strategic and critical engagement of AI in the writing tasks.

In the initial phase, a large number of participants (16 out of 18) admitted using AI to produce extended text, reflecting a lack of confidence in their writing capacities. For instance, Participant 7 noted that "at first, I used AI mainly for generating paragraphs because I lacked confidence in my academic writing."

As students gained more experience in writing skills, their use of AI became increasingly selective and purposeful. Instead of allowing AI to complete the whole writing practices, they now merely used it to evaluate coherence and improve language structure. To illustrate, Participant 2 described this change, noting that AI is used as "a sophisticated research assistant" to help with "logic checking and sentence restructuring". Likewise, Participant 15 highlighted a move towards greater independence, saying that they use "only for ideas and grammar" in order to support their writing development. This shift reflects increased learner agency and metacognitive awareness in AI-assisted writing.

4.3. Theme 3: Psychological Empowerment: Confidence and Reduced Anxiety

Besides cognitive support, AI was linked to positive psychological outcomes. In particular, participants consistently reported that AI increased their confidence and reduced stress when doing academic writing practices, especially in foreign language context.

Several participants (e.g. P1, P2, P4, P8, P12, P14, P15, P18) indicated that their confidence in their writing had enhanced. Particularly, Participant 2 reported that "AI has significantly refined my language and boosted my confidence"; in the meantime, other participants noted that they felt more confident about the accuracy and clarity of their writing.

Furthermore, many students (e.g. P4, P7, P13, P15, P18) also highlighted the role of AI in reducing anxiety. For example, Participant 7 explained that "knowing I can revise and refine my work with support reduces anxiety", making their academic work "more efficient and less stressful". Overall, these findings suggest that AI tools support writing performance and boost emotional experience in academic writing.

4.4. Theme 4: Assertion of Authorship and Ethical Boundaries

Despite their frequent use of AI in the academic writing process, students showed a strong and clear awareness of authorship and academic integrity. What is worth mentioning is that all participants emphasised that they remained responsible for their own work.

Many participants consistently identified themselves as the primary authors who retain control over ideas, arguments and final decisions. For instance, Participant 14 stated "the responsibility for the arguments, structure, and accuracy of the work remains mine" while Participant 2 highlighted that "AI only acts as a tool to polish my original work".

Moreover, many students actively set clear ethical boundaries for their use of AI. Many participants reported avoiding AI in reflective writing tasks to maintain authenticity and personal voice. To illustrate, Participant 7 noted that they "avoid using it for highly personal reflective essays" to ensure authenticity. Similarly, a large percentage of students (except P2 and P6) noted that they refused to use AI during examinations in order to comply with the institutional regulations. In short, these findings suggest student self-regulation and ethical awareness when using AI in their work.

4.5. Summary

Overall, the findings above reveal a consistent pattern in which AI is perceived as a supportive tool that enhances both cognitive and emotional dimensions of academic writing. At the same time, students strongly maintain awareness of authorship and thereby actively regulate their use of AI in line with personal and academic integrity standards.

5. Discussion

The findings of this study offer important insights into how students experience and interpret the use of AI tools in academic writing in higher education context. From the perspective of Sociocultural Theory (SCT), the results can be explained through key concepts, such as mediation, scaffolding and learner agency while also reflecting the features of EFL contexts in Vietnam in particular and Asian countries in general.

5.1. AI as a Mediational Tool and Scaffolding Mechanism

In response to the first research question, the results suggest that students consistently view AI as a multifaceted writing assistant that facilitates various stages of the writing process, rather than replacing human cognition. Based on SCT, AI can be conceptualised as an effective mediational tool that reshapes how learners approach complicated academic tasks. By reducing lower level linguistic concerns, such as grammar and vocabulary, students can concentrate more on cognition-requiring activities, namely idea development and argumentation.

While prior studies have described AI as a form of cognitive support (Kasneci et al., 2023; Dwivedi et al., 2023), the findings of this study suggest a more context-specific role. In EFL settings like in Vietnam, AI appears to be increasingly necessary, as students depend on it for academic lexical resources that are beyond their reach. This finding implies that AI not simply improves learner performance, but also facilitates their participation in academic discourse. Thus, AI functions not merely as a support tool but as a mediational scaffold that expands learners' capacity to participate within their ZPD. Therefore, pedagogically, instead of discouraging AI use entirely, lecturers may adopt structured activities involving brainstorming and outlining with AI assistance into early writing stages, which may help novice writers engage more effectively with academic writing tasks. Especially for first-year students who frequently struggle to generate and organise ideas, AI may play an important role in offering guided pre-writing resources. However, rather than simply copying AI-generated suggestions, students should be required to revise, improve and further develop them with their own thinking, so that they remain actively and critically engaged in the idea generating process.

All in all, AI is not just a powerful tool for improvement, but also a condition that allows learners to engage in academic writing in linguistically constrained contexts.

5.2. The Appropriation of AI Tools: From Dependence to Critical Engagement

The shift from early dependence on AI to more strategic use depicts a dynamic scaffolding process within the ZPD. In fact, students initially heavily depend on AI-generated content due to limited confidence and language ability, which reflects a large amount of external support from this technology. At this stage, AI proves to be a powerful tool that enables students to complete tasks beyond their ability. However, over time, this dependence gradually reduces when students begin to allocate the use of AI for more selective purposes, namely evaluating logical coherence or refining structures. This change indicates a gradual fading of scaffolding and increased self-regulation.

These findings question the concerns that the use of AI may lead to long-term dependency (Kasneci et al., 2023). Instead, these findings can be better understood as a developmental phase, where scaffolding is initially necessary but slowly and progressively fades as students gain competence. This interpretation can also be observed in recent studies about the student engagement with AI in education (Cañete et al., 2026; Park, 2024). This finding suggests that AI-mediated dependence should not be viewed as an inevitable and fixed outcome but instead as a transitional stage within a scaffolding process that supports students developing their self-regulated writing skills.

Based on the findings, the author suggests that instructors should set more focus on teaching their students how to critically integrate AI into their writing skills, rather than simply permitting or restricting AI use. For instance, lecturers can ask students to work in groups to analyse AI-generated texts, identify weaknesses in content or reasoning in the beginning and finally revise the drafts using their own ideas and knowledge. In this way, students may srengthen their analytical skills and promote their active engagement in the writing process, and thereby avoid excessive reliance on AI-generated content.

On the whole, lecurers' directions on appropriate AI usage may help students take advantage of this modern technology to develop their writing skills without becoming over-reliant on it.

5.3. Psychological Support and the EFL Writing Context

In addition to cognitive support, AI also significantly influences students' emotional experiences in writing. Students' reported increased confidence and reduced anxiety indicate that AI serves as an affective scaffolding that supports learners in both task performance and emotional regulation.

When viewed through the lens of SCT, especially in EFL settings, concerns about linguistic accuracy can be interpreted as a breakdown in mediation, where language acting as a mediational tool fails to support cognitive activities. In other words, writing anxiety can limit students' ability to perform effectively within the ZPD, preventing them from engaging with complex ideas. By providing immediate feedback and support, AI reduces emotional barriers, allowing students to actively participate in complex academic writing. As a result, AI may expand the ZPD by lowering both cognitive and emotional difficulties.

While prior studies have emphasised improvements in writing quality by AI (Baidoo-Anu & Ansah, 2023; Delikoura et al., 2025; Kasneci et al., 2023), this study suggests a deeper and more fundamental change in how learners experience writing. Nonetheless, this result also raises another concern: If students' confidence depends largely on AI, they may develop a reliance on external scaffolding both cognitively and affectively.

According to the findings, writing teachers may integrate AI-supported activities into introductory academic writing phases. For example, students can be asked to use AI to generate an outline or revise a draft and then reflect on how they modified the AI-generated suggestions. Indeed, these activities may help reduce writing anxiety and increase confidence while encouraging active engagement in the writing process. However, after the outlining sections, students should be required to independently complete writing tasks using their modified suggestions to prevent over-reliance on AI.

In short, while AI plays a significant role in expanding the ZPD by lowering both cognitive and emotional barriers, it may also cause students to rely on external support for their confidence, rather than on their own competence.

5.4. Authorship, Agency, and Ethical Boundary-Making

Despite frequent use of AI, students continue to position themselves as the main authors. This finding suggests that AI does not reduce their control, but changes how they manage the writing process, as students themselves decide when and how AI is used.

Setting ethical boundaries (e.g. Students reported not using AI in reflective writing tasks) reflects their self-regulation within a mediated context. Students actively decide when scaffolding by AI is necessary and when it should be withdrawn, showing awareness of their ZPD and responsibility for their writing.

At the same time, the combination of frequent AI use and strong claims of authorship implies how students redefine text ownership. Accordingly, authorship is no longer understood as working independently, but as controlling how AI is used and how meaning is made.

This finding is in line with recent studies about concerns regarding academic integrity in AI-assisted writing (Cotton et al., 2023; Chan & Hu, 2023). Furthermore, this result offers a more nuanced interpretation that students actively shape AI's role in their writing outputs, rather than passively relying on it.

The findings highlight the need for clearer guidelines on AI use in academic writing. In paricular, instructors can provide students with concrete examples of acceptable and unacceptable AI practices. For example, students may be allowed to use AI for brainstorming, outlining and language revision, but not for generating ideas or substantial sections of an assignment. This may help students make ethical decisions about AI use, and at the same time ensuring that the ideas expressed in their writing remain original. Not only in class, it is necessary that universities and institutions establish clear policies on the responsible use of AI in academic writing. Such methods should help recognise the ethical boundaries and raise awareness about maintaining their ownership.

As a result, learner agency is not reduced in AI-mediated writing but transformed into the ability to manage AI use and its support within the ZPD.

6. Conclusion

This research offers a deep insight into how English-major students at HUFLIT experience using AI-based tools in academic writing. Based on the qualitative data from 18 participants, the findings show that AI has become an indispensable part in students' academic writing practices in an EFL setting.

First, students consistently perceive AI as a multifaceted writing assistant that facilitates idea generation, organization and language refinement. Second, the research also reveals a transition from early reliance to more strategic and selective use of AI, suggesting that students develop self-regulation within ZPD. Third, besides cognitive support, AI functions as an affective reliever that reduces anxiety and enhances confidence in academic writing activities. Last but not least, students show a strong sense of authorship and actively establish ethical boundaries to maintain academic integrity.

These findings theoretically contribute to SCT by demonstrating that AI-mediated writing is not only about improving performance but also functions as a developmental process shaped by mediation and scaffolding. Practically, the findings suggest that AI should be integrated into EFL writing context as a supportive tool. To put it differently, institutions should guide students to use AI strategically, especially for prompting and critical feedback. Although the findings indicate that AI reduces anxiety and hence improves academic

performance, its use should be gradually withdrawn to promote self-regulation within the ZPD. In addition, universities are advised to establish clear and context-sensitive guidelines to ensure learners' integrity. Overall, the primary challenge is to integrate AI in educational context appropriately to achieve learning benefits and maintain academic integrity.

This study is limited by several issues. First of all, its small sample size (18 participants) and its focus on one single context at HUFLIT may prevent the findings from being transferred to other educational settings. Besides, the aim of qualitative design is to provide in-depth insights into participants' experiences rather than broad generalisation. Next, the cross-sectional design captures students' perceptions at a single point in time; therefore, the findings might not fully reflect how their engagement with AI evolves. Further research should apply longitudinal designs and include a broader range of participants from various institutions in Vietnam to explore how students' pattern of AI use and their perspectives towards this phenomenon develop over time and ensure the richness of findings.

In conclusion, students' engagement with AI in writing practices demonstrates a balance between technological support and individual agency, emphasising the importance of guiding students how to use AI in academic writing responsibly and strategically.

Phan Ngoc Phuong Vy received her Bachelor's degree in English Language Teacher Education from Ho Chi Minh City University of Education and her Master's degree in Applied Linguistics from Curtin University. She is currently a lecturer at the Faculty of Foreign Languages, Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT). Her academic interests include English language pedagogy, language teaching methodology, academic writing, and technology-enhanced language learning. Her research focuses on teaching and learning practices in English language education, particularly the integration of digital tools and emerging technologies to support student learning.

Appendices

Appendix A: Semi-structured Interview Questions

1. Can you tell me about your experience with academic writing at university?
   - What kinds of writing tasks do you usually do?
2. Can you describe how you first started using AI tools for academic writing?
   - What motivated you to try them?
   - Who or what influenced your decision?
3. Can you walk me through how you typically use AI in a writing assignment?
   - At what stage do you usually use it? (brainstorming, drafting, revising, proofreading)
4. Can you describe a recent writing task where you used AI?
   - What did you ask the AI to do?
   - What did you do with the AI-generated content?
5. How do you usually interact with AI tools when writing?
   - Do you modify your prompts?
   - Do you critically evaluate or edit the AI's responses?
6. Has your way of using AI changed over time? Why?
- What has changed?
7. Are there situations where you choose not to use AI? Why?
8. How do you see the role of AI in your academic writing?
   - Do you see it as an assistant, collaborator, shortcut, or something else?
9. In what ways do you think AI shapes or transforms your approach to academic writing?
   - Does it influence your ideas, structure, language, or confidence?
10. How do you feel about relying on AI for writing tasks?
    - Do you ever feel dependent on it?
11. What concerns, if any, do you have about using AI in academic writing?
    - Academic integrity?
    - Skill development?
    - Fear of detection?
12. When using AI, who do you feel is the main author of the text? Why?
13. How do you think using AI affects your development as a writer?
    - Do you feel it helps you learn, or does it reduce your learning?
14. Is there anything else about your experience using AI for academic writing that you would like to share?

#21 EFL-TO-ESL REPOSITIONING THROUGH TEACHER DEVELOPMENT: IMPLICATIONS FOR INTERNATIONALIZED EDUCATION AND WORKPLACES

Nguyễn Hưng Bình[1]

Abstract

Amid accelerating globalization, English is increasingly repositioned from a foreign language to a functional second language, yet the effectiveness of teacher professional development in enabling this shift remains uneven. This study investigates how professional development influences EFL-to-ESL repositioning and its alignment with internationalized education and workplace demands across four high schools in Vietnam and the Philippines. Adopting a mixed-methods, multi-site case study design, the research integrates survey data, interviews, and classroom observations. Findings reveal that sustained, context-sensitive professional development significantly enhances communicative pedagogy, fostering stronger alignment with real-world language use. Institutional disparities highlight the role of resources and professional learning cultures in shaping outcomes. The study contributes empirically grounded insights into scalable teacher development models, informing policy and practice in internationalizing education systems.

Keywords: alignment, internationalization, professional development, repositioning

TÁI ĐỊNH VỊ VAI TRÒ TỪ EFL ĐẾN ESL THÔNG QUA PHÁT TRIỂN ĐỘI NGŨ GIÁO VIÊN: HÀM Ý QUỐC TẾ HOÁ GIÁO DỤC VÀ NHIỆM SỞ

Tóm tắt

Trong bối cảnh toàn cầu hóa đang gia tăng nhanh chóng, tiếng Anh ngày càng được định vị lại từ một ngoại ngữ thành một ngôn ngữ thứ hai mang tính chức năng, tuy nhiên hiệu quả của hoạt động phát triển chuyên môn giáo viên trong việc thúc đẩy sự chuyển đổi này vẫn chưa đồng đều. Nghiên cứu này khảo sát cách thức phát triển chuyên môn ảnh hưởng đến quá trình định vị lại từ EFL sang ESL và sự phù hợp của quá trình này với các yêu cầu quốc tế hoá giáo dục và nhiệm sở tại bốn trường trung học ở Việt Nam và Philippines. Áp dụng thiết kế nghiên cứu tình huống đa địa điểm theo phương pháp hỗn hợp, nghiên cứu kết hợp dữ liệu khảo sát, phỏng vấn và quan sát lớp học. Kết quả cho thấy hoạt động phát triển chuyên môn được duy trì và phù hợp với bối cảnh đã nâng cao đáng kể phương pháp giảng dạy giao tiếp, thúc đẩy sự gắn kết chặt chẽ hơn với việc sử dụng ngôn ngữ trong thực tế. Những khác biệt giữa các cơ sở giáo dục làm nổi bật vai trò của nguồn lực và văn hóa học tập chuyên môn trong việc định hình kết quả. Nghiên cứu đóng góp những hiểu biết có cơ sở thực nghiệm về các mô hình phát triển giáo viên có khả năng mở rộng, qua đó cung cấp cơ sở cho chính sách và thực tiễn trong quá trình quốc tế hóa các hệ thống giáo dục.

Từ khóa**:** sự phù hợp, quốc tế hóa, phát triển chuyên môn, định vị lại

1. Introduction

1.1. Background:

Across rapidly globalizing economies, English is increasingly repositioned from a foreign language to a functional second language embedded in education and work. In Southeast Asia, this shift is particularly visible as schools respond to internationalization agendas and evolving workplace language demands that prioritize communicative competence, intercultural awareness, and digital fluency. In Vietnam and the Philippines, English occupies distinct yet converging roles within national curricula, creating a fertile ground to examine how pedagogical transformation unfolds in practice. Teacher professional development has emerged as a central lever in this transition, equipping educators with the capacity to integrate learner-centered approaches, technology-enhanced instruction, and contextually relevant language use. However, the extent to which such development initiatives effectively support the EFL-to-ESL repositioning remains uneven and underexplored. The selection of Phenikaa High School (PHS) in Hanoi and Tam Duong High School (TDHS) in Phu Tho Province reflects contrasting urban–rural contexts within Vietnam, while Far Eastern High School (FEHS) and Philippine Normal University High School (PNHS) represent established English-medium traditions in the Philippines. Together, these institutions provide a comparative lens to investigate how differing policy environments, resource availability, and professional learning cultures shape the enactment of English language repositioning in secondary education.

1.2. Aims:

Despite growing policy attention, a critical gap persists in understanding how teacher professional development concretely influences pedagogical shifts toward ESL-oriented practices and how these shifts correspond with internationalized education and workplace expectations. This study addresses this gap by examining two core questions: how teacher professional development influences EFL-to-ESL repositioning across selected high schools, and to what extent such repositioning aligns with broader global and occupational language demands. The research aims to identify key dimensions of effective professional development, analyze changes in teachers' instructional practices and beliefs, and evaluate the alignment between classroom language use and real-world communicative requirements. It is hypothesized that sustained, context-sensitive professional development significantly enhances ESL-oriented pedagogy and fosters stronger alignment with international and workplace standards. The study holds significance for policymakers, educators, and curriculum designers by offering empirically grounded insights into scalable models of teacher learning and language policy implementation. Ultimately, by bridging institutional practices with global demands, this research seeks to inform more coherent strategies for English language education reform. These considerations collectively justify the necessity of conducting this multi-site case study in both Vietnam and the Philippines.

1.3. Method

This study adopts a mixed-methods, multi-site case study design to examine how teacher professional development shapes EFL-to-ESL repositioning and its alignment with internationalized education and workplace language demands. A convergent research framework integrates quantitative survey data with qualitative interview and classroom observation evidence, enabling triangulation across four institutions: PHS and TDHS in Vietnam, and FEHS and PNHS in the Philippines. Data were collected over twelve weeks through online platforms such as Google Forms, Zoom, and Microsoft Teams. The sample

comprises approximately 80 English teachers and 200 senior high school students, selected through purposive and stratified sampling to ensure contextual diversity. Instruments include structured questionnaires measuring pedagogical beliefs and practices, semi-structured interviews exploring professional development experiences, and observation checklists assessing ESL-oriented instructional behaviors. Quantitative data are analyzed using descriptive and inferential statistics, including regression analysis to determine the impact of professional development on pedagogical shifts. Qualitative data are coded thematically to capture patterns in teacher cognition and classroom enactment. Instrument reliability is established through pilot testing and Cronbach's alpha, while validity is ensured via expert review and data triangulation. All participants provided informed consent, and participation was entirely voluntary. To safeguard confidentiality, all data were anonymized and encrypted, reinforcing ethical compliance and enhancing the credibility and transparency of the findings.

2. Literature review

Grounded in sociocultural and professional identity frameworks, this review synthesizes prior scholarship to contextualize EFL-to-ESL repositioning through teacher development. Studies were purposively selected based on relevance to teacher identity, professional learning, and alignment with global language demands across Asian contexts. Both empirical and theoretical works employing qualitative, quantitative, and mixed-methods designs are examined. Analytical focus is placed on conceptual definitions, methodological rigor, and reported impacts on pedagogy, thereby establishing a coherent foundation for comparative, multi-site investigation in this study.

Findings from Aultan, A. et al. (2020), Malaysia-based, investigated how sociocultural environments shape EFL-to-ESL transitions and teachers' professional identity. Using qualitative interviews and narrative inquiry, the study conceptualizes identity as socially constructed and context-dependent. Findings reveal that exposure to ESL environments enhances teachers' adaptability and communicative orientation. However, limited institutional support constrains identity transformation. While offering valuable sociocultural insights, the study lacks cross-national comparison and quantitative validation. This gap justifies examining how structured professional development systematically supports repositioning across varied institutional contexts in the present research. Besides, Ling, C. (2021), conducted in China, explores emotional dimensions in EFL/ESL teachers' identity development through a psychological lens. Employing survey and interview methods, the study defines emotions as mediators of professional growth. Results indicate that positive emotional engagement strengthens pedagogical commitment and identity reconstruction. Nonetheless, the research focuses primarily on internal factors, overlooking structural influences such as training systems. Its limitation lies in the absence of linkage between emotions and instructional outcomes, thereby necessitating further investigation into how professional development integrates affective and pedagogical dimensions. Echoing earlier studies, Xiaodong, L. (2022) provides a comprehensive theoretical review of EFL/ESL teacher professional development, synthesizing diverse approaches including reflective practice, mentoring, and technology integration. The study conceptualizes professional development as a continuous, multidimensional process influencing teaching quality. While it outlines significant impacts on pedagogy, it remains largely conceptual without empirical validation. Additionally, the review does not explicitly address alignment with workplace demands. This limitation underscores the need for data-driven studies examining how professional development translates into measurable ESL-oriented practices in real educational settings.

In their analysis, Sayit, A. et al. (2025), based in Indonesia, employed a quantitative design to assess the impact of teacher professional development on instructional practices and student achievement. Using statistical analysis, the study demonstrates a strong positive relationship between training and improved teaching outcomes. However, its focus remains within EFL contexts, without addressing ESL repositioning or global alignment. Moreover, contextual variables are minimally explored. These constraints highlight the necessity for broader comparative research linking professional development to both pedagogical transformation and internationalized language demands. Similarly, Xiaolin, L. (2023) theorized the interplay among professional identity, agency, and positioning within EFL contexts. Drawing on discourse analysis and conceptual synthesis, the study emphasizes teachers' active role in negotiating pedagogical change. While it advances theoretical understanding, empirical application is limited. The absence of concrete classroom evidence and cross-contextual comparison restricts its practical implications. Consequently, further research is required to operationalize these constructs within real-world ESL transitions, particularly through structured professional development initiatives examined in this study. Moreover, Yusnamariah, M. et al. (2025), Malaysia, analyze current trends in English teacher professional development through literature review and survey data. The study identifies shifts toward digital integration, collaborative learning, and lifelong professional growth. Despite its breadth, it lacks focus on EFL-to-ESL repositioning and does not examine workplace alignment. Furthermore, contextual disparities across institutions are underexplored. These gaps reinforce the need for targeted empirical studies investigating how contemporary professional development models influence ESL-oriented pedagogy and global communicative competence.

In a study conducted by Nguyen Van Thong et al. (2023) in Vietnam, they examined lesson study as a model for teacher development using qualitative case study methods. Findings highlight reflective practice and peer collaboration as catalysts for pedagogical improvement. However, the study is limited to a single national context and focuses primarily on instructional reflection rather than ESL repositioning. Its narrow scope suggests the necessity for comparative, multi-site research linking professional development approaches to broader internationalization and workplace language outcomes. Furthermore, Cong Khanh Ly (2022), Vietnam, investigated learners' beliefs about English as a global language using survey methodology. The study defines English as a tool for global communication and mobility. Findings reveal increasing recognition of its practical value among students. Nevertheless, the research does not address teacher development or pedagogical transformation. This limitation indicates a gap in connecting learner perceptions with instructional practices, supporting the rationale for examining teacher-driven ESL repositioning in the present study. Last but not least, Emma, D. (2021) explored English-Medium Instruction and teacher development within internationalization agendas through survey-based research in higher education. The study highlights the importance of training in enhancing instructional effectiveness and global alignment. However, it focuses on tertiary contexts and does not address secondary education or EFL-to-ESL transitions. Additionally, workplace alignment is implied rather than empirically measured. These gaps justify extending the investigation to high school settings and explicitly examining alignment with real-world language demands.

Collectively, prior studies emphasize teacher identity, professional development, and global English usage, yet remain fragmented across theoretical, emotional, and pedagogical dimensions. Few integrate these aspects within a coherent framework linking professional development to ESL repositioning and workplace alignment. Empirical evidence is often context-specific, lacking cross-national comparison and multi-site validation. Moreover,

alignment with real-world communicative demands is insufficiently operationalized. Addressing these gaps, the present study investigates how structured professional development drives EFL-to-ESL repositioning and its alignment with internationalized education and workplace expectations across diverse institutional contexts, offering novel comparative and practice-oriented contributions.

3. Results and findings

3.1. Quantitative data analysis

The results section presents quantitative and qualitative evidence examining the influence of teacher professional development on EFL-to-ESL repositioning and its alignment with internationalized education and workplace language demands across four high schools in Vietnam and the Philippines.

Table 1. Professional development impact on ESL repositioning

School	Mean score (%)
PHS	78
TDHS	65
FEHS	85
PNHS	88

(Source: Author, 2026)

Table 1 indicates clear cross-site variation in the impact of teacher professional development on EFL-to-ESL repositioning. PNHS records the highest mean (88%), followed by FEHS (85%), demonstrating strong ESL-oriented pedagogical transformation aligned with communicative and workplace demands. In contrast, PHS shows moderate impact (78%), while TDHS reports the lowest (65%), suggesting limited repositioning capacity in less-resourced contexts. These findings confirm that sustained, context-sensitive professional development significantly enhances ESL practices and better aligns classroom instruction with internationalized education and real-world language use expectations. Descriptive statistics reveal noticeable variation in the perceived impact of teacher professional development across institutions. As illustrated, mean scores for professional development impact on ESL-oriented pedagogy range from 65 at TDHS to 88 at PNHS, indicating stronger pedagogical transformation in Philippine contexts.

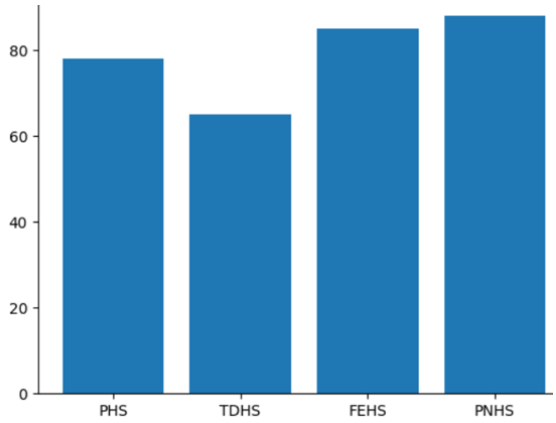

Figure 1: Personal development impact on ESL repositioning (Source: Author, 2026)

Figure 1 illustrates notable disparities in the impact of professional development (PD) on ESL repositioning across the four schools. PNHS achieves the highest score (88%), closely followed by FEHS (85%), indicating the strong effectiveness of PD in fostering communicative, ESL-oriented practices. PHS demonstrates a moderate level (78%), suggesting partial alignment with internationalized education demands. In contrast, TDHS records the lowest score (65%), reflecting constraints in translating PD into practice. Overall, the pattern confirms that sustained and context-responsive PD significantly enhances pedagogical shifts toward ESL and workplace-relevant language use. The data indicate that schools with sustained and structured professional development programs demonstrate higher levels of ESL-oriented instructional practices. Classroom observations confirm that teachers in FEHS and PNHS more frequently employed communicative tasks, authentic materials, and interaction-based techniques, whereas TDHS exhibited more traditional, grammar-focused instruction.

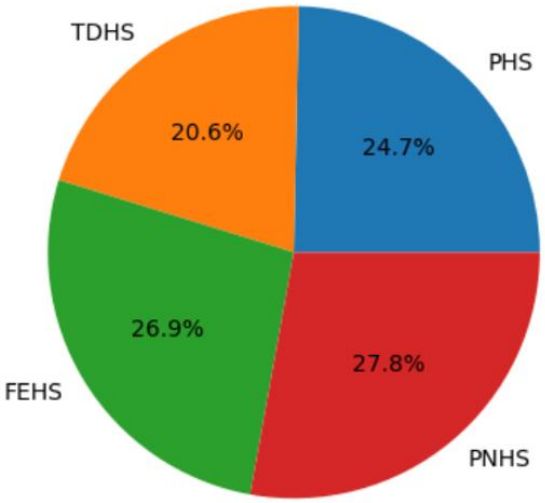

Figure 2: Distribution of PD impact (Source: Author, 2026)

Figure 2 presents the proportional distribution of professional development (PD) impact on ESL repositioning across the four schools. PNHS accounts for the largest share (27.8%), followed by FEHS (26.9%), highlighting the Philippines' stronger alignment with ESL-oriented practices. PHS contributes 24.7%, indicating moderate influence, while TDHS represents the smallest proportion (20.6%), reflecting comparatively limited PD effectiveness. This distribution reinforces that more robust and sustained PD frameworks are associated with greater pedagogical transformation and closer alignment with internationalized education and workplace communication demands. The chart demonstrates that PNHS and FEHS together account for over half of the total impact, reflecting their institutional emphasis on continuous teacher training and internationalized curricula. In contrast, TDHS contributes the smallest proportion, highlighting disparities in access to professional learning opportunities.

Table 2. Alignment with internationalized education and workplace demands

School	Alignment Score (%)
PHS	70
TDHS	60
FEHS	82
PNHS	86

(Source: Author, 2026)

Table 2 reveals clear differences in the degree of alignment between ESL repositioning and internationalized education and workplace demands across the four schools. PNHS records the highest alignment score (86%), followed by FEHS (82%), indicating strong responsiveness to global communication standards. PHS shows a moderate level (70%), suggesting partial integration of workplace-oriented language practices. In contrast, TDHS reports the lowest score (60%), reflecting limited alignment. These findings suggest that stronger professional development contributes significantly to enhancing alignment with international and occupational language requirements. Further analysis examines alignment with internationalized education and workplace language demands. As presented, alignment scores follow a similar pattern, with PNHS (86) and FEHS (82) outperforming their Vietnamese counterparts.

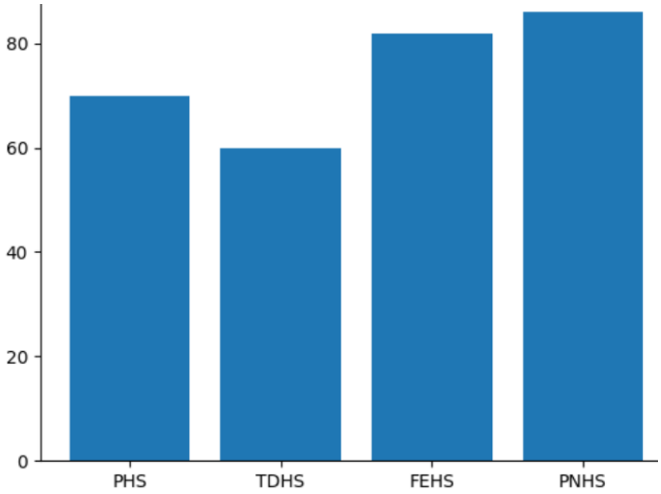

Figure 3: Alignment with workplace demands (Source: Author, 2026)

Figure 3 demonstrates varying levels of alignment between ESL repositioning and workplace language demands across the four schools. PNHS achieves the highest score (87%), followed by FEHS (82%), indicating strong integration of communicative and job-relevant language skills. PHS records a moderate level (70%), suggesting partial alignment with international workplace expectations. In contrast, TDHS shows the lowest score (60%), reflecting limited capacity to connect classroom practices with real-world language use. Overall, the results highlight that stronger professional development correlates with better workplace-oriented ESL alignment.

Inferential statistical analysis further supports these observations. Regression results indicate a strong positive relationship between teacher professional development and ESL repositioning ($\beta = 0.72$, $p < 0.01$), suggesting that professional learning significantly predicts pedagogical transformation. Similarly, professional development is moderately correlated with alignment to workplace language demands ($r = 0.65$), indicating that improved teaching practices contribute to more relevant language use.

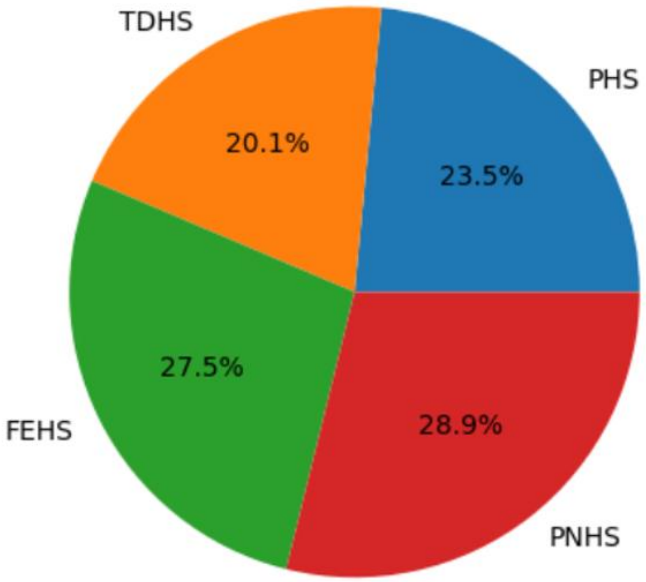

Figure 4: Alignment distribution (Author, 2026)

Figure 4 shows the distribution of alignment between ESL repositioning and workplace language demands across the four schools. PNHS accounts for the largest proportion (28.9%), followed by FEHS (27.5%), indicating stronger responsiveness to global workplace communication needs. PHS represents 23.5%, reflecting moderate alignment, while TDHS contributes the smallest share (20.1%), suggesting limited integration of practical language use. Overall, the distribution confirms that higher levels of professional development are associated with more effective alignment with internationalized education and workplace expectations. This visualization confirms that Philippine institutions demonstrate stronger alignment with global communication requirements, likely due to their longer-standing integration of English as a medium of instruction.

3.2. Qualitative data analysis

Qualitative findings from interviews provide further insight into these patterns. Teachers in high-performing schools reported increased confidence in facilitating communicative learning environments and integrating technology into instruction. They emphasized the role of ongoing mentoring, peer collaboration, and reflective practice in sustaining pedagogical change. Conversely, teachers in lower-performing contexts cited limited training duration, lack of institutional support, and curriculum constraints as barriers to effective ESL repositioning. Student responses also reflect these differences. Learners in FEHS and PNHS reported higher engagement in speaking and collaborative tasks, as well as greater exposure to real-world language scenarios. In contrast, students in TDHS indicated a stronger focus on exam preparation and limited opportunities for authentic communication.

Overall, the findings demonstrate that teacher professional development plays a significant role in facilitating the transition from EFL to ESL across diverse educational contexts. The data consistently show that schools with more comprehensive and sustained professional development initiatives achieve higher levels of pedagogical transformation and stronger alignment with international and workplace language demands. From a Vietnam-focused perspective, the results highlight the need to strengthen teacher development systems, particularly in rural or resource-constrained settings. While PHS demonstrates promising progress, the gap between Vietnamese and Philippine institutions suggests that further

investment in training quality, duration, and contextual relevance is necessary. Importantly, the study underscores that professional development must move beyond theoretical instruction toward practical, classroom-based application to achieve meaningful ESL repositioning.

In summary, the findings directly address the research questions by demonstrating that teacher professional development significantly influences EFL-to-ESL repositioning and that such repositioning is positively associated with alignment to internationalized education and workplace communication needs. These results provide robust empirical support for the study's hypothesis and offer actionable insights for educational policy and practice.

4. Conclusion

Findings from this multi-site investigation substantively clarify how teacher professional development shapes the repositioning of English from an EFL orientation toward an ESL paradigm across contrasting educational contexts. The evidence indicates that sustained, context-responsive professional learning fosters a decisive shift from form-focused instruction to communicative, interaction-driven pedagogy. Teachers who engaged in iterative training, mentoring, and reflective practice demonstrated greater capacity to integrate authentic materials, digital tools, and task-based activities, thereby aligning classroom discourse with real-world language use. Conversely, limited or fragmented development constrained pedagogical transformation, maintaining exam-oriented practices and restricting learners' communicative exposure. These patterns directly answer the first research question by confirming that the depth, continuity, and contextualization of professional development determine the extent of EFL-to-ESL repositioning. Furthermore, the convergence between greater pedagogical change and higher alignment with internationalized education and workplace demands addresses the second question, suggesting that ESL-oriented instruction operates as a mediating mechanism linking teacher learning to employability-relevant competencies. Theoretically, these findings extend models of language policy enactment by foregrounding teacher agency as a critical driver of systemic change. Practically, they underscore the necessity of long-term, practice-embedded development frameworks capable of translating policy aspirations into classroom realities. Collectively, the study contributes a nuanced comparative perspective, highlighting how institutional conditions and professional cultures shape the trajectory of English language transformation in internationalizing education systems.

Limitations: Despite its contributions, the study is not without limitations. The sample size, while sufficient for exploratory analysis, remains relatively modest and may limit generalizability beyond the selected institutions. Contextual differences between urban and rural settings, as well as national policy environments, may also introduce variability not fully captured in the design. Additionally, reliance on self-reported data alongside observations may involve response bias. The cross-sectional timeframe further restricts the ability to assess the long-term sustainability of pedagogical change.

Recommendations: Future research should adopt longitudinal designs to examine the durability of EFL-to-ESL repositioning over time and across broader institutional contexts. Expanding the sample to include additional regions and school types would enhance comparative validity. Practically, education systems should prioritize sustained, context-sensitive professional development models that integrate mentoring, peer collaboration, and classroom-based application. Policymakers are encouraged to align teacher training with evolving workplace language demands, ensuring that instructional practices remain relevant, adaptive, and responsive to global communicative expectations.

#23 Semiotics and Translanguaging Approaches to Inclusion and Critical Thinking in Generative AI Adoption

Fati Osuman[1]

Abstract

Generative Artificial Intelligence (Gen AI) in second language (L2) education offers new affordances for multilingual interaction, multimodal expression, and individualized feedback. However, concerns around academic integrity, erosion of critical thinking, equity, and the reproduction of cultural and linguistic bias remain underexplored. Existing technology-integration frameworks have been criticized for prioritizing tools over learner agency (Blundell et al., 2022), while recent pedagogical approaches incorporating translanguaging have not fully addressed assessment, reflection, or multimodal task design in AI-supported learning (Donley, 2024). Responding to these gaps, this conceptual paper proposes an inclusive framework for Gen AI–mediated task design grounded in translanguaging pedagogy and social semiotic theory. Drawing on current literature, the paper examines how Gen AI tasks designed through this lens can support three interrelated dimensions of learning: (1) critical thinking; (2) translanguaging and multimodality; and (3) equity and representation. The article concludes with implications and future directions for designing AI-supported language tasks that foster critical AI literacy, inclusion, and meaningful multilingual participation.

Keywords: generative AI, translanguaging, social semiotics, critical thinking, inclusive L2 pedagogy.

1. Introduction

Generative Artificial Intelligence (Gen AI), particularly tools like ChatGPT that generate new content through large-scale language modelling, has gained considerable attention in L2 for its potential to improve teaching and learning efficiency (Khonke & Zou, 2025). Gen AI enables language instructors to rapidly customise learning tasks, scaffold instruction, create multimodal materials, provide instant individualised feedback, and facilitate multilingual interaction in the classroom (Evmenova et al., 2024; Tang & Su, 2024). These affordances are particularly relevant in increasingly multilingual and international educational contexts where learners engage with diverse languages, identities, and modes of communication. While these opportunities open up new possibilities for language learning and feedback, concerns persist around academic integrity, data privacy, and the erosion of teacher autonomy (Crompton et al., 2024). Furthermore, overreliance on Gen AI risks undermining critical thinking development and exacerbating inequities for historically marginalised learners (Evmenova et al., 2024; Ahmed, 2025). These challenges imply that effective AI integration requires more than technological adoption. It thus requires pedagogical approaches that promote learner agency, critical engagement, and inclusion.

In the post-pandemic boom of Gen AI, frameworks like Substitution Augmentation, Modification Redefinition (SAMR) (Puentedura, 2013) guided technology integration but were criticized for prioritizing tool use classification over learner experience and pedagogical context (Blundell et al., 2022), leading scholars such as Donley (2024) to explore options such as translanguaging that centre inclusion and criticality. Donley (2024) used a teacher's qualitative data to show how translanguaging pedagogy guided Gen AI use in language

[1] *University of Ottawa, Canada, Email: fatymaosuman@gmail.com*

classrooms, focusing on three dimensions: affordances, production, and co-labour to promote inclusion and cultural competence. However, the study did not address assessment, reflections and multimodal task design, which are essential to counter overreliance and erosion of critical thinking. Consequently, there remains a need for conceptual frameworks that connect AI use with critical thinking, multilingual meaning-making, and equitable participation.

In response to the gaps identified, this article proposes a conceptual framework that applies translanguaging pedagogy and social semiotic theory to guide inclusive Gen AI-supported language learning. The framework positions learners as active meaning-makers who analyze, critique, and redesign AI-generated content while drawing on their full linguistic, cultural, and semiotic repertoires.

2. Conceptual Foundations

2.1. Translanguaging Pedagogy

It is a pedagogical practice that draws on multilingual learners' full linguistic and cultural resources to make sense of their world and communicate effectively (García, 2014). It fosters culturally responsive learning, reduces learner anxiety, and increases comprehension and participation (Cioè-Peña, 2022). Beyond language switching, translanguaging includes multimodal practices such as reading, writing, and dialogue for meaning-making, emotional expression and identity development (Galante, 2020). García and Kleifgen (2019) propose five dimensions for implementing translanguaging pedagogy in instruction: affordances, production, co-labor, assessment, and reflection. In terms of affordances and production, Gen AI tools can be used to generate multimodal input and support content creation that reflects students' cultural and linguistic identities. Co-labor can be fostered through collaborative, AI-supported learning that validates diverse knowledge systems. In assessment, educators adopt multimodal evaluation procedures that include translanguaging in formative and summative assessments. Reflection, on the other hand, involve examining cross-linguistic comparisons, language usage, and the sociocultural aspects of language to support deeper learning. These dimensions provide useful foundation for designing AI-supported language tasks.

2.2. Social *Semiotic Theory and Multimodality*

Semiotics is the study of signs and how meaning is created through them (Danesi, 2000). Social semiotics, introduced by Gunther Kress, shifts the focus from static sign systems to meaning-making as a dynamic, socially situated practice (Kress, 2010). Central to this approach is multimodality, which sees learning as designing meaning through selecting and reshaping semiotic resources such as images, language, sound, diagrams, and gestures (Adami et al., 2022). These resources carry culturally and socially embedded meanings, offering multiple entry points that make learning more accessible and inclusive. Wanselin et al. (2022) and Cheung et al. (2024) outline three key meaning-making layers relevant to Gen AI adoption in L2 tasks: presentational meaning (ideas, events, and participants), orientational meaning (attitudes, emotions, and perspectives), and organisational meaning (how elements connect to create coherence). Translanguaging and social semiotics combined position learners as analysts (critiquing Gen AI outputs for accuracy, representation, and bias), designers (revising, remixing or creating content), and advocates (producing work that reflects diverse identities). This approach fosters critical AI literacy while maintaining learner agency. When combined with translanguaging pedagogy, it offers a framework for critically evaluating and redesigning AI-generated content while supporting multilingual and multimodal expression.

3. Proposed Framework: Translanguaging and Social Semiotics for Inclusive AI Pedagogy

The proposed Gen AI adoption framework combines translanguaging pedagogy and social semiotic theory to guide inclusive and critical uses of Gen AI in L2 education. It treats AI outputs as semiotic resources that can be examined, critiqued, and transformed through multilingual and multimodal meaning-making. Three core aspects of learning underpin the framework: critical thinking, translanguaging and multimodality, and equity and representation.

3.1. Critical Thinking

A key challenge surrounding Gen AI in education is the potential for learner overreliance on AI-generated responses and limited autonomy. When students accept AI outputs uncritically, they miss opportunities for independent reasoning, evaluation, and knowledge construction. The framework addresses this challenge by positioning learners as critics of AI-generated content rather than passive recipients.

Drawing on the assessment and reflection dimensions of translanguaging pedagogy, learners are encouraged to examine how meaning is constructed in AI-generated texts, images, and other multimodal outputs. Social semiotics provides an analytical lens through which students can evaluate how information is presented (presentational layer), whose perspectives are represented (orientational layer), and how ideas are organized (organizational layer). For example, students might compare AI-generated responses across languages, identify inconsistencies or omissions, and revise outputs to better reflect particular cultural or contextual perspectives. Through these activities, learners develop critical AI literacy while engaging in higher-order processes such as analysis, evaluation, and redesign.

3.2. Translanguaging and Multimodal Meaning-Making

The framework also supports learner agency through multilingual and multimodal meaning-making. Translanguaging pedagogy encourages learners to mobilize their full linguistic and cultural repertoires when constructing knowledge, while social semiotics recognizes that meaning is communicated through multiple modes, including language, images, audio, and visual design.

Within AI-supported tasks, learners assume the role of designers who actively transform and remix content rather than simply consuming it. For example, teachers can use Gen AI to create scaffolded examples that students may use as a starting point for creating multilingual narratives, presentations, podcasts, or digital stories that reflect their experiences and identities. In doing so, they move across languages and modes to communicate meaning in ways that are personally relevant and culturally situated. Such activities extend language learning beyond traditional text-based tasks and create opportunities for creativity, collaboration, and multimodal literacy development.

3.3. Equity and Representation

A third dimension of the framework addresses equity and representation. As Gen AI systems are trained on large datasets that may privilege dominant linguistic and cultural perspectives, AI-generated outputs can reproduce existing biases and marginalize underrepresented groups. To address this, task design should centre cultural representation, inclusivity and accessibility. Through a translanguaging lens, tasks should encouraged

students to draw on diverse linguistic and cultural resources to challenge dominant narratives and contribute alternative viewpoints. Learners may analyze AI-generated texts for cultural assumptions, identify missing perspectives, and redesign content to better reflect their communities and lived experiences. In this way, students become advocates who use AI not only to access information but also to question, reshape, and expand it. Equity also involves ensuring meaningful participation in AI-supported learning. Educators must consider differences in digital access, technological familiarity, and language backgrounds when designing tasks. Providing multiple pathways for engagement and recognizing diverse forms of expression can help ensure that AI-enhanced learning environments remain accessible and inclusive for all learners.

Table 1

Summary of how translanguaging pedagogy and social semiotics can inform AI-supported task design in L2 education.

Translanguaging Dimension	Semiotic Focus	AI-Supported Strategy	Illustrative Task
Affordances	Multimodal input	Generate multilingual and multimodal content	Analyze AI-generated bilingual dialogue for tone and cultural meaning
Production	Presentational meaning	Co-create and adapt content using multiple languages and modes	Develop a multilingual travel blog incorporating visuals and local expressions
Co-labor	Organizational meaning	Support collaborative writing and revision	Co-author a digital story using AI-generated prompts
Assessment	Orientational meaning	Provide formative feedback on multimodal work	Revise an audio-visual reflection using AI feedback and self/peer-assessments
Reflection	Critical meaning-making	Critique and redesign AI-generated content	Rewrite an AI-generated text to address bias or missing perspectives

4. Implications and Conclusion

As Gen AI becomes increasingly adopted in language education, there is a growing call for pedagogical approaches that move beyond technological integration toward critical and inclusive learning. The framework proposed in this article responds to this need by integrating translanguaging pedagogy and social semiotic theory to support critical engagement, multilingual meaning-making, and equitable participation in AI-supported learning environments.

For language educators, the framework offers a practical approach to task design that positions learners as critics, designers, and advocates rather than passive consumers of AI-generated content. By encouraging learners to analyze, revise, and transform AI outputs through multiple languages and modes of communication, educators can promote learner agency, critical AI literacy, and deeper engagement with language and culture. Such an

approach is particularly relevant in multilingual and international educational contexts where learners bring diverse linguistic, cultural, and experiential resources to the classroom.

The framework also highlights the importance of addressing issues of equity and representation in AI-supported learning. Educators should critically examine how AI-generated content reflects particular cultural perspectives and create opportunities for learners to challenge, expand, and reinterpret these representations. In doing so, AI can become a tool for inclusion rather than the reproduction of existing inequalities.

Future research should examine the implementation of this framework in classroom settings and explore its impact on critical thinking, multilingual participation, and learner engagement. Additional research is needed to investigate how learners at different proficiency levels interact with AI-supported translanguaging and multimodal tasks, as well as how such approaches may support diverse and historically marginalized learner populations.

In positioning AI as a resource for critical inquiry, multilingual expression, and inclusive participation, this framework contributes a theoretically grounded approach to responsible AI integration in language education.

Fati Osuman obtained her PhD in Spanish (Linguistics) from the University of Ottawa, Canada. She is a language educator and researcher with over seven years of experience teaching Spanish and English across diverse levels and settings in Canada, the United States, and Ghana. Her research explores second language education and assessment, particularly where they intersect with inclusive technology and AI. Her dissertation examined student engagement in different Spanish learning formats, and her recent work investigates how generative AI can support language learning through translanguaging and plurilingual approaches.

#24 Activity Theory as a Lens for Examining Teachers' Enactment of the Competency-Based English Teaching Curriculum

Thanh Vinh Chau[1], Thao Quoc Tran[2]

Abstract

Competency-based reform has increasingly influenced language education, placing communicative competence at the center of curriculum development. In Vietnam, this orientation is reflected in the Competency-Based English Teaching Curriculum (CBETC). Despite growing interest in curriculum reform, limited attention has been paid to how CBETC enactment can be understood theoretically. Drawing on curriculum enactment scholarship, which conceptualizes curriculum as something interpreted, negotiated, and reconstructed in practice, this paper contends that existing accounts have tended to emphasize either procedural implementation or teachers' individual beliefs while paying insufficient attention to the wider social and institutional conditions surrounding classroom practice. In response, Activity Theory (AT) is advanced as a framework for examining the enactment of CBETC. Informed by Vygotsky's (1987) sociocultural perspective and Engeström's (2009) third-generation activity theory, the paper conceptualizes curriculum enactment as a socially mediated activity system shaped by the relationships among subject, object, tools, rules, community, and division of labor. The analysis illustrates how tensions and contradictions, particularly those arising from the coexistence of competency-based aspirations and examination-oriented traditions, influence teachers' pedagogical decisions and opportunities for professional action. By bringing AT into dialogue with scholarship on curriculum enactment, the paper offers a more comprehensive account of how curriculum reform is enacted in practice and contributes to ongoing discussions of competency-based English language education. The proposed framework also opens avenues for future empirical investigations of curriculum enactment in diverse educational settings.

Keywords: Activity Theory; curriculum enactment; competency-based education; English language teaching

1. Introduction

1.1. Global shift toward competency-based education

In the context of globalization and the rapid expansion of the knowledge-based economy, general education systems have been witnessing a marked shift from content-oriented models to competency-based approaches. International organizations such as the Organisation for Economic Co-operation and Development (OECD) emphasize that contemporary education should prioritize the development of learners' capacity to apply knowledge in practical situations rather than merely accumulate academic content (OECD, 2018). This global trend has significantly influenced curriculum reforms in many countries, including Vietnam.

Vietnam's 2018 General Education Curriculum represents a pivotal milestone by formally establishing the development of learners' qualities and competencies as its central orientation. Within this framework, English is designed according to communicative competence principles (Ministry of Education and Training [MOET], 2018). The introduction

[1] *Ho Chi Minh City Open University, Vietnam; Coresponding Email: thanhcv.24at@ou.edu.vn*
[2] *Ho Chi Minh City Open University, Vietnam*

of the CBETC, therefore, constitutes not simply an adjustment of content but a fundamental transformation in pedagogical orientation—shifting the focus from the transmission of linguistic knowledge to the development of learners' ability to use language effectively in authentic contexts.

1.2. The complexity of curriculum enactment

However, translating CBETC into classroom practice is not a linear process. Research on curriculum enactment suggests that teachers do not merely "implement" policy documents as written; instead, they interpret, adapt, and reconstruct the curriculum through their everyday instructional practices (Spillane, Reiser, & Reimer, 2002). The notion of enactment thus more accurately captures the dynamic and interactive nature of this process.

Teachers play a central role in transforming competency goals into concrete teaching activities while being influenced by multiple factors, such as professional beliefs, school culture, examination pressures, material conditions, and assessment policies (Priestley, Biesta, & Robinson, 2015). The interweaving of individual and contextual factors renders the enactment of CBETC a complex professional undertaking rather than a straightforward act of policy compliance.

1.3. The need for a comprehensive analytical lens

Linear approaches or those that focus solely on teachers' individual cognition often struggle to capture the systemic and evolving nature of curriculum enactment. A more comprehensive analytical framework is therefore required—one capable of examining the subject, mediating tools, rules, community, and the broader social relations that shape practice. In this regard, Activity Theory (AT), rooted in the socio-cultural tradition of Vygotsky (1987) and further elaborated in its third generation by Engeström (2009), provides such an approach. AT conceptualizes teaching practice as an activity system in which internal contradictions drive change and development.

1.4. Purpose of the paper

Building on the above arguments, this paper aims to examine the theoretical foundations of activity theory, analyze its role as an analytical lens for investigating teachers' enactment of CBETC, and discuss its theoretical and practical implications for curriculum development and teacher professional development.

2. Theoretical Background

2.1. CBETC and the motivation for its implementation

A CBETC can be understood as a curriculum approach in which the goal of instruction extends beyond the transmission of linguistic knowledge to the development of learners' ability to use English in specific communicative situations. From a competency-based perspective, learners are expected to mobilize knowledge, skills, and attitudes to accomplish learning tasks and address practical problems. This approach is consistent with global educational trends, as the OECD emphasizes that contemporary education should prepare learners with the capacity to act, adapt, and participate effectively in future social life (OECD, 2018).

In the Vietnamese context, CBETC is clearly reflected in the 2018 General Education Curriculum for English, issued together with Circular No. 32/2018/TT-BGDĐT. The curriculum states that English contributes to the formation and development of communicative competence through the four skills of listening, speaking, reading, and writing, while also supporting the development of learners' qualities, general competencies, and capacity for

lifelong learning (MOET, 2018). Accordingly, the focus of English language teaching has shifted from memorizing vocabulary, grammar, and test-taking techniques to organizing learning activities that enable students to use language purposefully, contextually, and meaningfully. Recent reviews of CBETC literature in Vietnam further indicate that this shift requires substantial changes in teachers' professional roles, moving from knowledge transmitters to facilitators of communicative learning, learning designers, and assessment mediators (Chau & Tran, 2026). This orientation is also aligned with the spirit of the Common European Framework of Reference for Languages, which emphasizes descriptions of language proficiency based on what learners are able to do in communication (Council of Europe, 2020).

However, CBETC does not automatically translate into classroom practice. Teachers are required to interpret competency-based objectives, select appropriate teaching materials, design communicative tasks, organize classroom interaction, and assess students' progress. Therefore, the enactment of CBETC should be viewed as a process of professional construction shaped by teachers' beliefs, school conditions, assessment pressures, and learning culture.

In contemporary educational research, curriculum is no longer understood as a static document or a fixed body of content to be transmitted directly from policy to classroom practice. Rather, it is increasingly viewed as a social and situated practice constructed, interpreted, and reconstructed through the interaction among teachers, students, and contextual conditions. From the perspective of "curriculum as practice," curriculum comes into being only when it is enacted in specific educational settings (Priestley, Biesta, & Robinson, 2015). In this sense, teachers are not passive implementers of prescribed policy documents; they are professional agents who interpret curricular intentions, select appropriate content, adapt pedagogical strategies, and respond to learners' actual needs (Chau & Tran, 2026).

The enactment of a CBETC should therefore be understood as a dynamic process through which teachers transform competency-oriented goals into concrete classroom practices. This understanding is also reflected in recent studies on CBETC enactment, which identify teachers' beliefs, classroom practices, and contextual conditions as interconnected dimensions shaping curriculum enactment processes (Chau & Tran, 2025b). Unlike traditional content-based approaches that mainly emphasize the transmission of grammar, vocabulary, and linguistic knowledge, CBETC requires teachers to organize learning activities that develop students' ability to use English meaningfully in communicative contexts. This means that teachers must translate broad curricular objectives, such as communicative competence, learner autonomy, collaboration, and problem-solving, into instructional tasks, classroom interaction, assessment practices, and learning support.

The notion of enactment is particularly useful because it moves beyond the linear idea of implementation. While implementation often suggests a direct movement from curriculum policy to classroom application, enactment emphasizes interpretation, negotiation, adaptation, and reconstruction (Spillane, Reiser, & Reimer, 2002). In the context of CBETC, teachers are simultaneously shaped by official curriculum documents and actively involved in re-creating them through their beliefs, pedagogical experience, professional knowledge, school culture, examination pressure, available resources, and students' learning characteristics.

Therefore, the enactment of CBETC is not merely a technical matter of following curriculum guidelines. It is a complex professional activity situated at the intersection of individual agency and broader institutional structures. Teachers must balance competency-oriented expectations with contextual realities, including large class sizes, limited teaching time, traditional assessment practices, and learners' varying levels of English proficiency. To understand this multidimensional process, a theoretical framework is needed that connects

teachers' classroom actions to the social, cultural, and institutional conditions that shape them. Activity Theory provides a particularly relevant foundation for examining the enactment of CBETC as a socially mediated, contextually situated activity system.

2.2. Overview of activity theory

2.2.1. Sociocultural foundations (Vygotskian roots)

Activity Theory originates from the sociocultural tradition of Vygotsky, who argued that higher mental functions are mediated by cultural tools and signs within social contexts (Vygotsky, 1978). Rather than conceptualizing cognition as a purely internal process, Vygotsky maintained that human action is always shaped by culturally constructed means such as language, symbols, documents, and material artifacts. The concept of mediation thus becomes foundational to AT, underscoring the idea that individuals do not interact directly with the world but do so through mediating tools.

Moreover, tool use does not merely facilitate action; it also transforms the subject who acts. Tools are simultaneously products of cultural-historical development and instruments that shape how individuals think and behave. This insight is particularly significant in educational settings, where curricula, textbooks, instructional materials, and assessment policies function as mediating tools within teaching practice.

In addition, learning is conceptualized as a socially situated process. Knowledge is constructed through interaction within communities of practice rather than existing independently within individuals. This perspective provides a basis for analyzing the classroom as a social activity system in which teachers and students collaboratively construct meaning.

2.2.2. First and second generations of activity theory

Building on Vygotsky's foundational principles, Leontiev extended AT by distinguishing between activity, action, and operation, thereby emphasizing the goal-directed nature of human activity (Leontiev, 1978). This distinction suggests that activity is always oriented toward an object, an element that generates both motivation and meaning for human action.

Subsequently, on this theoretical foundation, Yrjö Engeström developed the second generation of AT by constructing the well-known expanded triangular model of the activity system (Engeström, 1987). This model comprises the following core components:

- Subject
- Object
- Tools (mediating artifacts)
- Rules
- Community
- Division of labor

By incorporating social dimensions such as rules, community, and division of labor, AT moves beyond individual, level analysis and enables the examination of action in relation to institutional and cultural structures. In educational research, this model is particularly valuable for analyzing teaching practice as a complex system in which teachers do not act independently but are influenced by multiple interacting forces.

2.2.3. Engeström's third-generation activity theory

In the third generation, Engeström (2009) further expanded AT to analyze interactions among multiple activity systems. Rather than focusing on a single activity system, as in earlier versions, Engeström proposed a model of interacting activity systems, which is especially suitable for contexts of educational reform, where policy, school, and classroom can be conceptualized as interconnected systems.

In addition, a significant contribution of the third generation is the concept of expansive learning. According to this perspective, learning is not merely the acquisition of existing knowledge but a process of reconstructing the object of activity through the resolution of internal contradictions. Contradictions are viewed as the driving force for change and development within activity systems. For example, in the context of the CBETC, the contradiction between the goal of developing communicative competence and grammar-oriented assessment practices may create tension while simultaneously opening up opportunities for innovation in teaching practice.

By emphasizing the role of contradictions and transformation, third-generation AT provides a dynamic analytical lens through which curriculum enactment can be understood not as passive adaptation but as a developmental process of reconstruction. This perspective is particularly relevant to research on the enactment of CBETC, where teachers continuously adjust their practices to respond to policy demands and contextual constraints.

In sum, Activity Theory offers a comprehensive theoretical framework for analyzing teachers' curriculum enactment as a socially situated activity system, highlighting the roles of mediation, context, and contradiction in professional development and educational change.

2.3. Applying activity theory to teachers' enactment of CBETC

2.3.1. Conceptualizing CBETC enactment as an activity system

Based on Engeström's (2009) analytical framework, the process of teachers enacting the CBETC can be conceptualized as an activity system in which its components interact dynamically.

First, the subject of the system is English language teachers—the professional agents who directly interpret and actualize the curriculum in classroom practice. They do not merely transmit content; instead, they make pedagogical decisions grounded in their experience, beliefs, and contextual conditions. Second, the object of the activity is the development of students' English communicative competence in alignment with the orientation of the new general education curriculum. This object is dynamic and may be reconstructed in practice, for instance, when teachers shift their focus from communicative competence development to ensuring examination performance. Third, the tools include textbooks, curriculum guidelines, policy documents, instructional technologies, and pedagogical strategies. From Vygotsky's (1978) perspective, these tools function as mediating artifacts that shape how teachers organize learning activities.

In addition, rules encompass assessment regulations, school culture, professional standards, and societal expectations. These rules either support or constrain the enactment of competency-oriented activities. The community consists of students, colleagues, school leaders, and parents—stakeholders who participate in or influence the enactment process. Finally, the division of labor reflects the allocation of roles among teachers, subject departments, and school leadership in organizing and supervising instructional activities. Conceptualizing CBETC enactment as an activity system allows for the simultaneous analysis

of individual and structural factors, rather than reducing the issue to teachers' personal competence alone.

2.3.2. Mediations and interactions within the activity system

Within this system, components do not exist in isolation but continuously interact and mediate one another. Instructional tools, such as competency-oriented textbooks, may encourage teachers to organize communicative activities, project-based learning, or formative assessment. However, tool use is not mechanical; teachers may reinterpret materials in light of their own experience and beliefs. According to Spillane et al. (2002), policy implementation is inherently a process of "sense-making," in which teachers interpret and adapt policy messages within specific contexts.

Rules also function as critical mediating elements. In educational contexts strongly influenced by high-stakes examinations, the pressure to achieve high scores on standardized tests may lead teachers to prioritize grammatical structures over the development of communicative competence (Chau & Tran, 2025a). This illustrates how the interaction between the object (competency development) and rules (knowledge-oriented assessment) can transform the orientation of activity.

Moreover, community and division of labor shape how teachers enact the curriculum. Professional support from subject departments, structured professional meetings, and leadership direction may create enabling conditions for methodological innovation. Conversely, a lack of coordination or unclear role allocation may undermine the effectiveness of enactment. As argued by Priestley et al. (2015), teacher agency is always formed within an ecological relationship between individuals and their contexts.

2.3.3. Contradictions and tensions in CBETC enactment

One of the key contributions of AT is its conceptualization of contradictions as drivers of change (Engeström, 2009). In the context of CBETC, the following three typical contradictions can be identified.

The first concerns the tension between the goal of communicative competence development and an assessment system oriented toward grammatical knowledge. Within the AT framework, this represents a contradiction between the object and rules of the activity system. In practice, when examinations continue to emphasize linguistic structures, teachers may adjust their instructional activities to meet assessment demands, thereby weakening the coherence of the competency-based curriculum (Chau & Tran, 2025a).

The second contradiction lies between innovative pedagogical approaches (e.g., project-based learning, group work, formative assessment) and contextual constraints such as large class sizes, limited instructional time, or insufficient technological resources. This reflects tensions among tools, rules, and the material conditions embedded within the community.

The third is an internal contradiction among teachers, specifically between beliefs in communicative language teaching and entrenched traditional teaching habits. According to Leontiev (1978), the motive of activity may shift when the object is reconstructed; thus, the tension between long-term professional goals and short-term performance pressures may lead to adjustments in pedagogical action. These contradictions should not be viewed solely as barriers but as potential sources for restructuring the activity system.

2.3.4. Expansive possibilities and transformation

From the perspective of expansive learning proposed by Engeström (2009), when contradictions are identified and critically reflected upon, they may become resources for innovation. For example, pressure arising from misalignment between competency goals and assessment formats may motivate teachers to seek alternative assessment approaches, such as task-based or portfolio assessment. However, such transformation requires specific enabling conditions, including: professional spaces for teachers to discuss and reflect; more flexible assessment policies; school leadership that encourages pedagogical experimentation; and the development of professional learning communities.

Accordingly, only when the components of the activity system are more harmoniously aligned, for instance, when rules are consistent with the object and tools genuinely support competency goals, CBETC enactment achieves greater sustainability. Therefore, Activity Theory not only facilitates the description of practice but also provides an analytical foundation for guiding systemic change.

In sum, applying Activity Theory enables the conceptualization of teachers' enactment of CBETC as a complex activity system in which mediating factors, contradictions, and social interactions jointly shape instructional practice. This approach clarifies the dynamic, contextualized, and developmental nature of curriculum enactment within the broader context of educational reform.

2.4. Roles of Activity Theory in Understanding CBETC Enactment

2.4.1. Providing a holistic analytical framework

One of the significant contributions of AT to research on CBETC enactment lies in its capacity to provide a comprehensive analytical framework. Rather than focusing solely on teachers' cognition or individual beliefs, AT situates teaching practice within a broader activity system, where the subject's actions are always mediated by tools, rules, community, and the division of labour (Engeström, 1987).

In many studies on curriculum reform, cognitively oriented approaches tend to explain variations in practice primarily through "teacher beliefs" (Borg, 2003; Fives & Gill, 2015; Spillane, Reiser, & Reimer, 2002). However, as Spillane, Reiser, and Reimer (2002) argue, policy implementation is not merely a matter of understanding or misunderstanding policy texts; it is a process of interpretation situated within specific social contexts. AT enables researchers to move beyond this reductionist view by conceptualizing teachers as acting subjects embedded in institutional and cultural ecosystems.

When applied to CBETC, Engeström's (1987) analytical framework facilitates the simultaneous integration of structural factors—such as assessment regulations, professional standards, and examination pressures—with cultural elements, including established teaching traditions, parental expectations, and students' learning habits. Consequently, enactment is not reduced to a question of the degree of compliance with curricular prescriptions; rather, it is understoodas a socially negotiated and continuously restructured practice.

This holistic approach is particularly well-suited to the context of educational reform in Vietnam, where CBETC is implemented within a system long shaped by an examination-oriented model of teaching and learning. AT makes it possible to analyse the relationship between competency-oriented goals and existing assessment structures as components of a single activity system, rather than as isolated factors.

2.4.2. Capturing complexity and non-linearity

A second contribution of AT lies in its capacity to capture the complexity and non-linearity of curriculum enactment. In practice, enactment does not unfold according to a simple cause–and–effect sequence. Instead, it is shaped through dynamic interactions among multiple components within the activity system.

Grounded in Vygotsky's (1978) sociocultural theory, AT posits that human action is always mediated by tools and social context. This implies that changes in one component (e.g., modifications in assessment formats) may lead to adjustments in other components (e.g., instructional strategies). The expanded triangular structure of the activity system provides a means of representing these multidirectional interactions.

Moreover, third-generation AT emphasizes interactions among multiple activity systems (Engeström, 2009). In the case of CBETC, at least three interrelated systems can be identified: the policy system (ministerial level), the school system, and the classroom system. These systems do not operate independently; instead, they continuously influence one another. For example, changes in national assessment policy may reshape teachers' objectives of activity at theclassroom level.

AT thus helps avoid a linear conception in which policy is "transmitted" from the top and implemented intact at lower levels. Instead, enactment is understood as the outcome of ongoing negotiations between structural forces and individual agency. This perspective is critical in the study of CBETC, a reform that requires coordinated changes in objectives, content, pedagogy, and assessment.

2.4.3. Identifying sources of change and development

Another notable contribution of AT is its ability to identify sources of change and development through the concept of contradictions. According to Engeström (2009), internal contradictions within an activity system are not merely obstacles but also drivers of expansive learning.

In the context of CBETC, contradictions—such as the misalignment between competency-oriented goals and knowledge-focused testing practices—can serve as productive points of analysis. Rather than interpreting such tensions as evidence of teachers' failure, AT encourages their recognition as indicators of systemic imbalance. Analysing contradictions between the object (competency development) and the rules (traditional assessment practices) makes it possible to illuminate structural constraints that must be addressed for the curriculum to function effectively.

This perspective carries important implications for teacher professional development. When teachers engage in reflective examination of contradictions in their practice—for instance, through professional learning communities or lesson study—they may reconstruct the object of their activity and develop new forms of practice. Professional growth, therefore, is not simply the accumulation of instructional techniques; it is a transformative process that reconfigures the activity system in alignment with curricular goals.

AT thus offers an analytical lens that is both diagnostic and developmental. It enables the identification of bottlenecks in CBETC enactment while also pointing toward conditions for sustainable change, including adjustments to assessment regulations, strengthened professional support, and the cultivation of collaborative learning communities within schools.

In summery, activity theory functions as a robust theoretical framework for understanding CBETC enactment in three respects: it provides a holistic perspective that moves beyond individual cognition; it captures the complexity and non-linearity of the enactment

process; and it identifies sources of change through the analysis of systemic contradictions. In doing so, AT not only clarifies the nature of teaching practice in reform contexts but also informs strategies for curriculum development and teacher professional learning.

3. Methodology

This study was conducted as a theoretical analysis to clarify the role of Activity Theory in examining teachers' enactment of the competency-based English teaching curriculum. Instead of collecting empirical data from classroom settings, the paper focuses on analyzing, synthesizing, and interpreting research studies and theoretical papers related to competency-based curriculum, curriculum enactment, communicative competence in English language teaching, and Activity Theory. This approach is appropriate to the paper's purpose because the main focus of the study is not to measure the extent of curriculum implementation but to develop an analytical perspective capable of explaining the complex, socially situated, and context-dependent nature of CBETC enactment.

The main sources selected for analysis include foundational works on Vygotsky's sociocultural theory and Engeström's activity system model, studies on curriculum enactment by Spillane and colleagues, and documents related to Vietnam's 2018 General Education Curriculum for English. These materials were read and analyzed with a focus on identifying key concepts, including subject, object, tools, rules, community, division of labor, contradiction, and expansive learning. On this basis, the paper examines how these components can be applied to understand English teachers' instructional activity in the context of the shift from content-oriented to competency-based teaching.

The analytical procedure was carried out in three main steps. First, the paper clarifies the conceptual foundations of CBETC and the issue of curriculum enactment. Second, the components of Activity Theory are systematized and connected to the context of English language teaching in Vietnamese high schools. Third, the paper analyzes typical contradictions in the enactment of CBETC, particularly the misalignment between the goal of developing communicative competence and the pressure to test and examine linguistic knowledge. In doing so, the study proposes Activity Theory as an analytical lens that connects teachers' individual actions to broader institutional, cultural, and social conditions.

4. Results

4.1. Implications

4.1.1. Theoretical implications

The application of AT to the study of teachers' enactment of CBETC generates significant theoretical implications for the field of curriculum studies. First, AT reinforces the view of curriculum enactment as a structured social activity rather than a series of discrete individual actions. Drawing on Yrjö Engeström's (2009) model of the activity system, curriculum research can simultaneously analyse the subject, object, tools, rules, and community as elements of an integrated whole. This perspective broadens traditional approaches that have tended to focus primarily on content analysis or teachers' beliefs.

Second, AT contributes to research on competency-based education by offering a lens through which to interpret the discrepancy between policy intentions and classroom practice. In reform contexts, the shift from a knowledge-based model to a competency-based model frequently encounters an "implementation gap." Through the concepts of contradictions and expansive learning, AT enables the identification of internal systemic tensions as drivers of development rather than merely as indicators of policy failure (Engeström, 2009).

Furthermore, Vygotsky's (1978) sociocultural foundation underscores the role of mediation and context in the construction of practice. This reinforces the argument that research on CBETC must move beyond a purely technical perspective and instead examine the relationship between pedagogical action and institutional structures. In this sense, AT functions not only as a descriptive tool but also as a theoretical foundation that orients curriculum studies toward a systemic and developmental approach.

4.1.2. Practical implications

In addition to its theoretical contributions, the application of AT yields several practical implications for stakeholders involved in CBETC implementation.

For curriculum developers, AT suggests that curriculum design cannot be separated from the conditions of enactment. Consistency between competency-oriented goals (object) and the assessment system (rules) is essential to minimizing contradictions within the activity system (Chau & Tran, 2025a). This requires coherent alignment among content, pedagogy, and assessment, rather than reform limited to policy documents alone.

For school leaders, AT highlights the significance of community and division of labour in supporting teachers. Establishing professional learning communities, creating spaces for reflection, and encouraging pedagogical experimentation can assist teachers in addressing contradictions in practice. As Priestley, Biesta, and Robinson (2015) argue, teacher agency is formed within an ecological relationship between individuals and their contexts; consequently, the organizational environment plays a decisive role in the success of CBETC enactment.

Regarding teacher professional development, AT advocates a system-oriented, reflective approach rather than merely providing instructional techniques. By analysing contradictions between curricular goals and classroom realities, teachers can engage in expansive learning, reconstruct the object of their activity, and adjust pedagogical strategies. Professional development thus becomes a process of transforming the activity system, rather than simply enhancing individual skills.

4.1.3. Directions for future research

Although AT provides a robust theoretical foundation, further empirical validation is needed in specific contexts. The use of mixed-methods designs or in-depth case studies may clarify how components of the activity system interact and evolve over time. In addition, the development and validation of questionnaire instruments could provide a quantitative basis for examining factors affecting teachers' enactment of CBETC (Chau & Tran, 2025b). This is particularly important in the Vietnamese context, where disparities in infrastructure, learning culture, and local policy conditions remain substantial. Moreover, integrating AT with other theoretical frameworks—such as teacher agency or ecological approaches, may enrich the analysis and deepen understanding of teachers' roles within reform systems. Future empirical studies may also employ validated questionnaires to measure the extent to which beliefs, practices, impetus, and hindrances influence CBETC enactment (Chau & Tran, 2025b).

5. Discussion

A further contribution of this paper lies in highlighting the analytical value of contradictions in understanding CBETC enactment. Within Engeström's (2009) framework, contradictions are viewed as historically accumulated tensions that emerge among elements of an activity system and create possibilities for transformation. In the Vietnamese context, one of the most visible tensions concerns the coexistence of competency-oriented curricular goals

and examination practices that continue to reward the reproduction of linguistic knowledge. Such tensions suggest that difficulties in curriculum enactment cannot be reduced to teachers' individual limitations or resistance to change. Instead, they arise from the interaction between policy aspirations and institutional conditions.

This interpretation is consistent with a growing body of research in language education that has applied Activity Theory to investigate educational innovation and change. For example, Blin and Appel (2011) demonstrated that tensions among technological tools, institutional expectations, and established pedagogical routines significantly influence how language teachers respond to innovation. Their work illustrates how pedagogical change is shaped not only by teachers' intentions but also by the relationships among multiple elements within an activity system. Viewed from this perspective, the challenges associated with CBETC enactment reflect broader patterns identified in Activity Theory research, where curriculum innovation is frequently mediated by contextual constraints, competing priorities, and institutional arrangements.

The discussion also suggests that Activity Theory offers a broader explanatory framework than approaches centered primarily on teacher beliefs or cognition. While studies such as Borg (2003) and Fives and Gill (2015) have generated valuable insights into teachers' thinking, AT highlights the social, cultural, and organizational conditions in which those beliefs are formed and enacted. Rather than treating beliefs as isolated determinants of practice, Activity Theory positions them within a network of mediating influences, including institutional regulations, professional communities, material resources, and assessment systems. This perspective allows curriculum enactment to be understood as a socially situated process rather than solely an individual cognitive endeavor.

Consequently, supporting the enactment of CBETC requires more than methodological training. Sustainable curriculum reform depends on stronger coherence among curriculum objectives, assessment systems, school leadership, professional collaboration, and classroom realities. This view is also compatible with Priestley, Biesta, and Robinson's (2015) ecological understanding of teacher agency, as well as Chau and Tran's (2025b, 2026) argument that curriculum enactment should be examined through the relationship between teachers and the broader environments in which they work. Taken together, these perspectives reinforce the argument that teachers should be viewed as active participants in interconnected activity systems whose practices evolve through ongoing engagement with contextual opportunities and constraints. Effective enactment of CBETC, therefore, depends not only on teachers' professional capacities but also on the alignment of the wider conditions that support curriculum reform.

6. Conclusion

This article has argued that Activity Theory provides a productive analytical lens for examining teachers' enactment of CBETC. Through the activity system model, AT conceptualizes enactment as a complex social practice in which elements such as subject, tools, rules, and community continuously interact.

This systemic perspective moves beyond linear views of implementation by emphasizing the dynamic, non-linear, and contextually situated nature of teaching practice. At the same time, the concepts of contradictions and expansive learning open possibilities for identifying and guiding change within reform processes.

In the context of CBETC implementation, careful analysis of contextual factors—from assessment policy and school culture to classroom conditions—is a prerequisite for achieving

competency-development goals. The application of activity theory, therefore, not only facilitates a deeper understanding of practice but also informs strategies for sustainable improvement in general education.

Acknowledgments

The authors would like to express their sincere gratitude to Ho Chi Minh City Open University for providing academic support and a research environment that enabled the development of this paper. The authors are also grateful to colleagues and scholars in the field of English language education whose discussions and academic insights helped shape the theoretical orientation of this study. Special thanks are extended to those whose work on competency-based education, curriculum enactment, and Activity Theory provided an important foundation for the arguments presented in this article. Any remaining limitations or shortcomings are solely the responsibility of the authors.

#26 Enhancing Coherence and Cohesion in IELTS Writing through Generative AI Feedback: An Exploratory Study

Nhu Hoang Ngoc Quynh[1] & Sa Tran Si Nguyen[2]

Abstract

Improving coherence and cohesion (CC) in academic writing, especially for IELTS preparation, is challenging. It requires constructive feedback and sufficient practice, but time constraints often prevent teachers from properly assessing student's work. Generative AI models like ChatGPT can be an effective supplementary tool to assist students. This study examines how 20 students at Industrial University of Ho Chi Minh leverage this tool to enhance CC in their writing. Data was collected through comparing writing samples before and after ChatGPT intervention. Both versions of the essays were evaluated to identify any positive changes in cohesive devices and idea organization. Furthermore, questionnaires were conducted to gather students' experiences, strategies for using AI-generated feedback. The findings reveal both advantages and challenges of AI-generated suggestions on student's Cohesion and Coherence. This research seeks to provide meaningful insights into the role of generative AI, offering implications for English language teaching and learning.

***Keywords*:** cohesion and coherence, generative AI, ChatGPT, IELTS writing

1. Introduction

In the context of educational globalization and internationalization, IELTS certificate holds a more important role in evaluating a learner's English competency serving educational and professional purposes. Among four skills of the IELTS test, writing tends to be considered as the most difficult skill for EFL learners to acquire and master. According to IELTS performance statistics for Vietnamese test takers in the period 2024 - 2025, the average band score in Listening was 6.5, while Speaking had a lower mean of 5.6. Reading demonstrated relatively strong performance with an average of 6.4, while Writing fell behind at 6.1. This performance gap shows that writing continues to pose a significant challenge for Vietnamese EFL learners, thus emphasising the importance of providing learners with more specialised support and teaching methods aimed at enhancing learners' writing competence (Test taker performance 2024-2025, n.d.). One of the main causes of this difficulty is that writing requires managing both cognitive processes and advanced language use at the same time (Kormos, 2023). In addition to grammar, writing is about control over vocabulary, syntax, and discourse organisation. Learners are expected to effectively generate, organise, and articulate ideas in a logical sequence. For this reason, coherence and cohesion criteria, which refers to connections and organisation of ideas (Halliday & Hasan, 2014), are considered crucial and accounts for 25% of IELTS's total writing score. Hyland (2019) also affirms that in academic contexts like the IELTS Writing Task 2, coherence and cohesion are the primary evaluation (Hyland, 2019). Despite their importance, coherence and cohesion present considerable challenges for many EFL learners, particularly at intermediate and upper-intermediate levels (Banerjee & Wall, 2006; Schoonen et al., 2003). Traditional writing assessment approaches often focus on grammar and vocabulary development but fail to sufficiently provide individualised feedback on higher order writing skills such as organisation and textual flow (Hyland, 2003; Bitchener

[1] *Lecturer, Faculty of Foreign Languages, Industrial University of Ho Chi Minh, Ho Chi Minh City, Vietnam; Email: hnqnhu188@gmail.com*
[2] *Lecturer, Foreign Language Center, Ho Chi Minh University of Technology, Ho Chi Minh City, Vietnam*

& Ferris, 2012). In many instructional settings, teachers are limited by large-sized classes, limited time, and heavy focus on test-taking strategies, leaving little room for detailed feedback on discourse-level features (Bitchener & Ferris, 2012). As a result, learners frequently struggle to apply their linguistic knowledge into well-structured academic essays. Moreover, the subjective and complex nature of coherence and cohesion makes them difficult to address with traditional corrective feedback methods. Learners are usually given general comments such as "improve organisation" or "use more linking words" which do not provide detailed and practical guidance for revision. Consequently, there are limited opportunities for students to engage in cycles of writing and reflection, which are crucial for writing development (Hyland & Hyland, 2006).

Generative artificial intelligence (AI), particularly tools such as ChatGPT or Gemini, can serve as a promising solution. These AI models can produce contextual and human-like feedback in terms of organisation, argumentation, and clarity (Swiecki et al., 2022; Banihashem et al., 2024.; Shi & Aryadoust, 2024). When providing learners with immediate and personalised feedback, AI tools may create new opportunities for improving coherence and cohesion in IELTS writing, while also supporting learner autonomy and reflection. As such, the integration of GenAI in learning and teaching writing skill has increasingly gained attention from scholars in recent years.

Even though generative AI tools such as ChatGPT raise new possibilities, most studies focus solely on aspects such as accuracy in grammatical structures, profound vocabulary range, or overall quality of essays, ignoring discourse-level features, particularly cohesion and coherence. Furthermore, there is still limited empirical research on their effectiveness in improving higher order writing skills in IELTS preparation contexts. This study bridges this gap by investigating how AI-generated feedback influences learners' ability to enhance coherence and cohesion in IELTS Writing Task 2 essays and how learners perceive this type of support. In particular, the study seeks to explore how AI-generated responses can function as a tool to guide learners in better organising their ideas and ensuring greater clarity in their arguments. Beyond textual outcomes, the study also aims to explore learners' perceptions of AI feedback in terms of its usefulness and reliability as well as potential limitations (Steiss et al., 2024). Therefore, it contributes a balance between empirical evidence of writing improvement and an understanding of learners' learning experiences.

To achieve these objectives, the study addresses two central research questions:

1. To what extent does generative AI feedback enhance coherence and cohesion in IELTS Writing Task 2 essays?
2. How do EFL learners perceive the usefulness and reliability of generative AI feedback for improving their IELTS writing performance?

2. Literature Review

2.1. Feedback Intervention Theory (FIT)

Feedback has always been a pivotal aspect to enhance study quality, especially in learning and teaching writing. Of all theories regarding the role of feedback, Feedback Intervention Theory (FIT), proposed by Kluger and DeNisi (1996), posits that effectiveness of feedback is maximised when it helps learners realize the gap between their current performance and desired goals, thereby opting for plausible reactions to bridge this gap. According to FIT, feedback does not always work, if vague or overly critical ones are given, it causes

performance to decline. Instead, specific and corrective mistakes help learners know exactly how to fix the problem, hence improving the way learners perform.

In academic contexts, feedback is especially important since learners hardly realize weaknesses related to coherence and cohesion. As such, feedback that is specific, timely and able to orient reactions allows learners to make necessary adjustments in editing essays. The blooming growth of Generative Artificial Intelligence (GenAI) offers a new feedback form meeting various features of effective feedback following FIT. Unlike the traditional automatic writing assessment system which mainly focuses on grammar and vocabulary mistakes, large language models such as ChatGPT are capable of analyzing how arguments are structured, pointing out problems in flow of ideas and suggest how to improve them. Thanks to the ability of giving immediate and individualized feedback, GenAI is expected to assist learners in improving discourse-level aspects, especially coherence and cohesion. However, FIT also emphasizes that the efficacy of feedback depends not only on the quality of feedback but also on how users make use of feedback. As a result, to evaluate pedagogical value of GenAI, it is essential to consider both the improvement in writing products and the way learners perceive this feedback tool.

2.2. Coherence and Cohesion

In academic writing, beside concepts that are regularly emphasized by educators such as grammatical range, lexical resource, task response, and accuracy, the aspects of coherence and cohesion hold paramount significance as well. These two elements determine whether an essay is logical and whether ideas flow smoothly. It is no exaggeration to state that coherence and cohesion are the cornerstone of a high-band essay. Therefore, sufficient practice in organizing ideas logically and employing appropriate lexical and grammatical devices to enhance connection of sentences in text is indispensable.

Halliday and Hasan (2014) put forward intertwined terms cohesion and coherence. Cohesion concerns semantic meanings of a text. There are two major offshoots: lexical cohesive devices (reiteration and collocation) and grammatical cohesive devices (reference, substitution, ellipsis and conjunctions) to connect ideas both sentence level and paragraph level. Through cohesion texts are linguistically linked, forming a cohesive and interdependent structure (Janebi Enayat, 2025).

On the other hand, coherence refers to the unity of ideas in the paragraph. In this regard, the paragraph is linked smoothly and logically from topic sentence, to supporting sentence, detail sentences and concluding sentences. Oshima and Hogue (2006) propose four ways to achieve coherence: repeating key nouns, maintaining a consistent tone, using transition signals to connect ideas, and arranging ideas logically. When coherence is established, readers can effortlessly grasp the intended meaning of the text.

In the context of IELTS writing, achieving a higher band score (at least Band 6) means students have a good command of using Coherence and Cohesion as the band descriptor requires students to present their ideas in a clear, logical, and coherent manner. Javahery (2025)'s research put forward that essays which fail to exhibit clear progression of ideas and varied cohesive devices are likely to be given Band 6, instead of Band 7 or above. However, many students tend to focus primarily on other aspects of writing and overlook coherence and cohesion, which ultimately reduces their overall performance. There are innumerable research confirming the struggle of most students with utilizing cohesion and coherence in academic writing. A study of Rahman et al., (2023) unveil that although undergraduates majoring in English at Islamia College Peshawar attempt to use cohesive devices in their academic writing,

their application is mostly inappropriate, hindering achieving plausible coherence. This claim is echoed by Trang et al. (2023) and Anindita (2024), in which students are reported to encounter problems such as overuse and misuse conjunctions, reference, repetition and synonyms, and transition signals while underuse cohesive devices like substitution, and ellipsis as well as other types of coherent devices. Furthermore, some students admit they have yet developed a solid grasp of cohesion and coherence, with a few even confusing the two terms (Diep & Diep ,2024). The struggle in employing cohesion and coherence can be attributed to three main reasons: lack of motivation, limited lecture duration and prior English knowledge (Leli, 2020).

Many efforts have been devoted to improving cohesion and coherence in students' academic essays. Previous research has examined whether explicit and implicit instruction in cohesion and coherence can improve students' academic writing. Li and Chen (2026)'s research, which employs a controlled experimental design with 64 upper intermediate-level undergraduate students at a Chinese university, figures out the noticeable improvement in students' academic writing skills when coherence is explicitly taught. Similarly, writing abilities of Iranian EFL learners are proven to be enhanced when they are exposed to explicit instruction (Behbahani et al., 2018). Bahang et al. (2021) also found that teachers can raise students' awareness of how to structure essays logically by explicitly introducing effective coherence-building methods such as theme-rheme progression, which ultimately gives rise to higher writing performance. However, time constraints in classroom settings remain a persistent challenge, as teachers are often unable to provide comprehensive feedback on every essay or give tailored guidance on logical organization to each individual student's writing.

To address this limitation, alternative supports such as automated writing evaluation (AWE) systems and peer feedback have been proposed. Chen and Cui (2022) report that these approaches can foster certain improvements in students' cohesion and coherence. Similarly, Anindita (2024) demonstrates that tools like the Tool for the Automatic Analysis of Cohesion (TAACO), combined with peer feedback, can help identify common cohesive errors and provide systematic evaluations of student writing. Nevertheless, feedback generated by such tools is often too general, insufficiently constructive, and lacking in concrete suggestions for improvement. Peer feedback, while valuable, also has limitations. Termjai (2024) observes that students tend to focus more on grammar and vocabulary than on coherence and unity when providing comments, while Sun et al. (2023) further notes that many learners lack the knowledge necessary to give meaningful corrections or suggestions.

2.3. The integration of ChatGPT in improvement coherence and cohesion

To address these issues, ChatGPT has recently emerged as a viable substitute that is accessible to all students at any time and is increasingly perceived as accurate and reliable. Unlike earlier automated tools, ChatGPT, continuously updated and improved, can generate contextually relevant explanations, suggest personalized revisions, and respond interactively to students' prompts until they are satisfied with their refined drafts (Kohnke, Moorhouse, & Zou, 2023). A myriad of studies have shed fascinating light on the utilization of generative AI, particularly ChatGPT, to enhance learners' writing skills, not only for grammatical or vocabulary correction, but also for cohesion and coherence improvement. Li et al.'s (2023) findings demonstrate that ChatGPT is capable of generating essays that are not only flawless in grammatical structures and lexical resources but also meet academic standards of coherence and cohesion. Herbold et al. (2023) and Tengler and Brandhofer (2025) similarly argue that ChatGPT's essays resemble human writing because they employ logical connections, appropriate transitions, and ensure a smooth flow of ideas between sentences. Furthermore,

ChatGPT's feedback mechanism on coherence and cohesion offers considerable benefits for learners. As Sekewael and Anaktototy (2024) observe, students can input their own drafts and receive personalized, relevant, and real-time feedback. This immediacy enables them to revise their work, learn to think more logically, and strengthen the flow of ideas without having to wait days for teacher feedback, or in some cases, without receiving any feedback at all.

It can be concluded from the review that, although there is growing interest in employing AI-assisted writing tools, most existing research has concentrated on improving surface-level aspects such as grammar, vocabulary, or overall essay structure. Few studies have placed emphasis on the practical application of generative AI in enhancing discourse-level features, particularly cohesion and coherence, which are critical for academic writing and IELTS performance. Moreover, limited attention has been given to learners' real-time interactions with AI tools and their perceptions of such feedback. This highlights the need for research that explores the transformative power of generative AI feedback, specifically ChatGPT, in improving cohesion and coherence in IELTS writing from the learner's perspective.

3. Methodology

3.1 Pedagogical Setting & Participants

Participants were 20 third-year EFL students majoring in English Studies at the Industrial University of Ho Chi Minh City. Each of the participants are expected to reach at least a B1 Intermediate level on the Common European Framework of Reference for Languages (CEFR) since they are in their third year. The research setting was a six-week IELTS Writing Task 2 workshop integrated into the Discourse Analysis course. All students were required to achieve a minimum IELTS score of 6.5 for graduation, which provided a strong motivation for participation in this study.

3.2 Design of the Study

Our research employed a mixed-methods design, following Creswell and Plano Clark (2017). This approach combined quantitative and qualitative methods to investigate the role of generative AI feedback in enhancing the coherence and cohesion in IELTS Writing Task 2 essays. The rationale behind this design lies in the complementary strengths of both data types: quantitative analysis can be used to measure learners' performance improvement, while qualitative inquiry provides deeper insights regarding learners' perceptions and experiences. Following Li et al. (2023), mixed-methods designs are particularly appropriate for applied linguistics research because they allow researchers to reveal the complexity of second language learning phenomena by integrating measurable outcomes with learners' reflective perspectives.

3.3 Data Collection & Analysis

Two distinct IELTS Writing Task 2 essays were used as pre-test and post-test to measure improvement in 20 participants' writing performance. Every essay was evaluated using the official IELTS Writing Band Descriptors with a great emphasis on coherence and cohesion. Participants were provided with automated feedback generated by ChatGPT. The data collected included essay scores and responses from a post-intervention questionnaire designed to record learners' perceptions of AI-mediated feedback in academic writing.

The study lasted six weeks and followed a structured intervention process. During the first week, participants were required to write a pre-test IELTS Writing Task 2 essay, which was assessed using the official IELTS descriptors. From Weeks 2 to 5, classroom instruction focused on developing coherence and cohesion in academic writing. Each week, students

submitted essays to ChatGPT and received feedback on aspects such as organization, linking devices, and clarity. They then revised and resubmitted their drafts based on the AI-generated feedback. In Week 6, participants completed a post-test essay and a perception questionnaire in relation to the usefulness, reliability, and relevance of ChatGPT feedback.

The quantitative data consisted of learners' pre- and post-test scores in the area of coherence and cohesion. The normality of the difference scores was first assessed using the Shapiro-Wilk test. As the data violated the assumption of normality, the scores were then analysed using the Wilcoxon signed-rank test to determine whether there was a statistically significant improvement in writing performance. Statistical significance was set at $p < .05$. The qualitative data derived from the Likert-scale questionnaire, which explored students' frequency of ChatGPT use and their perceptions of its feedback, including its reliability and usefulness.

4. Results

This section interprets the findings from the quantitative and qualitative analyses of the study. The primary aim was to examine how generative AI feedback improved IELTS learners' coherence and cohesion in writing. Data were drawn from three key sources: (a) pre- and post-writing task scores assessed based on the IELTS Writing rubric, (b) detailed language analyses of textual features associated with coherence and cohesion, and (c) learner perceptions collected through a questionnaire. The three complementary sources provided a broader perspective on the impact of generative AI, enabling a profound understanding of its role in fostering learners' writing development.

Table 1

Shapiro-Wilk test for difference scores

	W	p
CC Post-test - CC Pre-test	0.8259	.002

The normality of the difference scores (post-test minus pre-test) for learners' CC scores was examined using the Shapiro-Wilk test.

As can be seen in Table 1, the Shapiro-Wilk test indicated that the distribution of the difference scores significantly deviated from normality, $W = .8259$, $p = .002$. Because the p-value was less than .05 and IELTS Writing band scores are reported on an ordinal 9-band scale, the assumptions required for a paired-samples t-test were not fully satisfied.

According to Bluman (1997), the Wilcoxon signed-rank test was selected to evaluate the difference between the pre-test and post-test CC scores. This is because it does not require the assumption of normality and is appropriate for paired ordinal data.

Table 2

Descriptive statistics and Wilcoxon signed-rank test results for learners' pre-test and post-test writing performance

Measure 1		Measure 2	W	z	p	Rank-Biserial Correlation
CC Post-test	-	CC Pre-test	210.0	3.92	<0.001	1.00

The Wilcoxon signed-rank test showed a statistically significant improvement over participants' Coherence and Cohesion scores after the intervention, $W = 210.0$, $z = 3.92$, $p < .001$. Moreover, the matched rank-biserial correlation indicated an extremely large effect size ($rrb = 1.00$), suggesting that the ChatGPT-based feedback had a high positive impact on all of the learners' coherence and cohesion in writing.

After analysing the before and after versions of student essays, there was a great reduction in errors related to the use of cohesive devices. In the first drafts, cohesive devices were used both inconsistently and often inappropriately. For example, students often overused basic connectors such as “because,” “besides,” and “and,” which led to repetitive sentence structures and a lack of logical link. On the other hand, misuse or omission of linking phrases resulted in abrupt transitions between ideas, thus decreasing overall coherence. A common instance was the overuse of additive markers (e.g., “besides”) where contrastive or causal links were needed.

In the revised versions, however, students used cohesive devices more accurately and diversely. Such markers as “for instance,” “as a result,” “on the other hand,” and “therefore” were properly utilised to signal cause and effect, exemplification, as well as contrast. Hence, it allows for a clear and logical progression of ideas and well-developed paragraphs. For example, in the food waste essay, the transition “as a result” replaced the less precise “because,” thereby enhancing logical flow. Similarly, in the zoo essay, the use of “however” and “nevertheless” made sharper contrasts between opposing viewpoints.

In terms of quantitative research, the number of cohesive device errors, including inappropriate use, omission, or redundancy, significantly decreased in the revised essays. In the first drafts, errors in cohesion were frequent and sometimes hindered meaning comprehension, contributing to lower band scores, approximately Band 5.5 to 6.0 for coherence and cohesion. In the final drafts, cohesive devices were both more diverse and contextually appropriate, resulting in better ratings of around Band 7.0 to 7.5 in this category.

These findings indicate that explicit feedback and revision contributed to improved control over cohesion. Students not only could reduce errors in basic connectors but also demonstrated an ability to use a wider range of cohesive devices to express complex logical relationships. This development suggests greater awareness of how cohesive devices lead to coherence, a key criterion in the IELTS Writing Task 2 rubric.

The comparative analysis of the students’ before and after versions showed vast improvements in not only logical flow but also paragraphing. In the first drafts, paragraphs often contained loosely connected ideas associated with limited development. For example, in the food waste essay, several reasons for food wastage were listed continuously without clear sequencing or elaboration, causing repetition rather than progression. Similarly, the topic sentences in the essays on education and technology were vague, and supporting details were not linked back to the main argument; thus, the cohesion between sentences in a paragraph was weak.

In the revised drafts, the paragraph structure was clearer, consisting of stronger topic sentences, supporting arguments, and concluding statements. Each paragraph developed a single controlling idea, and transitions between paragraphs reflected a more logical sequencing of arguments. For instance, in the public transportation essay, the revised version began with the short-term benefits of road expansion before contrasting them with the long-term sustainability of public transport. This arrangement produced a more balanced discussion and complied with the requirements for coherence and cohesion of IELTS Writing Task 2.

Furthermore, logical flow within paragraphs improved through the use of appropriate discourse markers and clearer cause and effect reasoning. In the after versions, students moved beyond merely listing ideas and instead created a logical chain of reasoning. Some students not only provided the reasons to open a zoo but linked the ethical considerations of keeping animals in captivity with conservation function in a proper flow and transition words such as “however” and “on the other hand” were used effectively.

As a consequence, the students’ control over coherence and cohesion was improved as ideas were presented in a logical order and arguments were more fully developed. This improvement suggests that students became more aware of effective paragraphing strategies, such as starting with clear topic sentences, maintaining progression, using transitions to guide the reader, and drawing a reasonable conclusion. Based on IELTS Writing Task 2 descriptors, this shift is more likely to raise scores in the Coherence and Cohesion from approximately Band 5.5 to 6.0 in the first drafts to Band 7.0 to 7.5 in the revised versions. Automated textual analysis using Coh-Metrix (Graesser et al., 2014) confirmed these findings, showing improved measures of referential cohesion and deep cohesion in the learners’ writing.

Questionnaire is also conducted to gain insights into how students perceive of using ChatGPT to enhance coherence and cohesion in their writing.

Table 3

Student’s frequency of using AI to study English

Frequency of Use	**Percentage**
Every day	40%
Several times a week	50%
Occasionally	10%
Do not use	0%

When students were asked about how frequently they use AI tools to support their English learning, half of the students (50%) reported using AI several times a week, while about 40% used it daily. A smaller proportion (10%) indicated only occasional use, and none reported not using AI at all. These findings highlight the growing prevalence of AI technology among university students and its potential for integration into English teaching and learning.

Table 4

Students’ Self-evaluation of cohesion and coherence in their essay

Evaluation Level	**Percentage**
Good	5%
Fair	50%
Average	45%
Poor	0%

Students have also been asked to self-evaluate coherence and cohesion aspects in their academic essays. Most of them highly rated their ability as either average or fair, with very few considering themselves good, and almost none identifying as poor. Although students

expressed confidence in their skills, analysis revealed a wide range of errors related to cohesion and coherence in their first version of essay. Even though they manage to use some cohesive devices, they show their inability to use a variety of devices. This wrong self-evaluation suggests that students are oblivious of their writing deficiencies, which AI tools like ChatGPT can help illuminate.

Table 5

Sources that students usually receive feedback when learning to write in English

Source of Feedback	Percentage
No feedback received	0%
Peer review (from classmates)	50%
Guidebooks or reference materials	30%
AI tools (e.g., ChatGPT, Grammarly, etc.)	95%
Teacher	55%

Regarding the ways from which students get feedback to refine their writing essays, most of the students agree that AI tools are the most commonly used source (95%), followed closely by teachers and peer reviews (50%). No respondents reported receiving no feedback at all. The crucial role of technology, particularly AI tools, in enhancing writing skills has become increasingly evident. Students are gradually turning to AI not only for research and entertainment but also for educational purposes. This shift reflects a reduced dependence on teachers and a growing reliance on alternative sources of support in learning English.

Table 6

Time Students Spent Using Chat GPT to Edit Essays

Time	Percentage
Under 10 minutes	10%
10-20 minutes	60%
20-30 minutes	25%
More than 30 minutes	5%

In the experiment, when students were instructed to use Chat GPT to revise cohesion and coherence in their essays, more than half of them (60%) dedicated only about 10-20 minutes interacting with Chat GPT to finalize their ideas, exactly 25% of students spent between 20-30 minutes using ChatGPT. While 10% of students only seek advice from Chat GPT in less than 10 minutes, 5% of students spend over 30 minutes communicating with this AI tool.

Table 7

Purposes of using Chat GPT to enhance CC

Purposes	Percentage

Suggest ways to use references	50%
Suggest ways to use ellipses	35%
Suggest ways to use collocations	55%
Find appropriate collocations	55%
Find appropriate reiteration to avoid repetition	60%
Ask ChatGPT to detect and revise inappropriate linking errors	90%
Help check the logical flow of the article	60%
Suggest how to present content and illustrative images	55%
Improve accuracy and writing style	40%
Ask ChatGPT to compare different versions to choose the more logical one	60%

As for what purposes they use ChatGPT for in the process of editing their essays to achieve coherence and cohesion, the most common purpose for which ChatGPT is utilized is to "Ask ChatGPT to detect and revise inappropriate linking errors", with 90% respondents indicating this use. Finding appropriate collocations and reiteration to avoid repetition (60%) are the second top choices. "Ask ChatGPT to compare different versions to choose the more logical one" also gains acclaim from 60% of learners as they might be confused if they have different ways to develop ideas. Conversely, the least common purpose is suggesting ways to use ellipses, reported by only 35% of respondents. This suggests that students may undervalue or lack awareness of ellipsis as a cohesive device.

Table 8

Students' Attitudes Towards Utilizing Chat GPT to Enhance CC in Ielts Writing

		n	M	S.D.
1	I intend to continue using ChatGPT afterwards	20	4.10	0.72
2	I feel that Chat GPT's feedback is easy to understand & apply	20	4.00	0.79
3	I'm excited when using ChatGPT to improve writing	20	4.05	0.60
4	I believe ChatGPT makes me more confident	20	4.05	0.60
5	I'm encouraged by ChatGPT feedback	20	3.90	0.85
6	I am demotivated when feedback is unclear	20	3.10	1.17
7	I think using ChatGPT is boring and monotonous	20	3.05	1.05

The table illustrates student's attitude when seeking for Chat GPT's assistance in giving feedback on their cohesion and coherence in Ielts Writing. Positive feedback such as "I feel that Chat GPT's feedback is easy to understand & apply", "I intend to continue using

ChatGPT" and " I'm excited when using ChatGPT to improve writing", are approved by most of the correspondents, with their means are 4.00, 4.10 and 4.05 respectively. Notably, negative statements such as "ChatGPT is boring and monotonous" or "I feel demotivated when feedback is unclear" received relatively low levels of agreement.

Table 9

Student's perceptions of Relevance and Usefulness

	n	M	S.D.
Using ChatGPT saves me time when editing my writing	20	4.20	0.77
ChatGPT gives useful suggestions to improve linking between sentences/paragraphs using cohesive devices	20	4.20	0.62
ChatGPT helped me see whether my ideas are clearly organized and logically connected (coherence)	20	4.00	0.56
I am complete in control when revising based on feedback, using prompts and exploring coherence strategies	20	3.90	0.64
After using ChatGPT, I can apply cohesion/coherence strategies to other essays without help	20	3.85	0.75
ChatGPT's feedback is comparable to or better than peers/teachers in some cases	20	3.75	0.72
ChatGPT's feedback fits common contexts in IELTS Writing Task 2	20	3.70	0.80

Table 9 presents students' perceptions of the relevance and usefulness of ChatGPT in enhancing coherence and cohesion in writing. The data indicate that users highly value ChatGPT for its time-saving benefits (M = 4.20) and its helpful suggestions for improving cohesion through the use of linking devices (M = 4.20). Other aspects, such as its ability to help students examine the coherence of their writing (M = 4.00) and the opportunity to actively engage with ChatGPT using prompts to revise essays (M = 3.90), also received strong approval. However, perceptions regarding ChatGPT's independence are more reserved. Statements like "ChatGPT's feedback is comparable to or better than peers/teachers in some cases" (M = 3.75) and "After using ChatGPT, I can apply cohesion and coherence strategies to other essays without help" (M = 3.85) received comparatively lower ratings. These findings suggest that students view ChatGPT primarily as a supplementary tool rather than a full replacement for traditional instruction or peer feedback.

5. Discussion

The findings from the essay versions and questionnaire offer valuable insights into the efficacy of using ChatGPT as a tool for enhancing coherence and cohesion in academic writing. Notably, learners demonstrated a statistically significant improvement in coherence and cohesion following the intervention ($W = 210.0$, $z = 3.92$, $p < .001$), with a very large effect size (rank-biserial correlation = 1.00). This empirical progress directly supports Javahery's (2025) assertion that mastering logical progression and cohesive devices is essential to break the Band 6 threshold. These improvements also parallel previous research demonstrating that focused instruction and practice can significantly enhance learners' discourse competence and coherence (Weigle, 2013).

Post-test essays revealed clearer paragraphing, smoother transitions between ideas, and more varied and accurate use of cohesive devices compared to pre-test essays, reflecting real

progress toward higher IELTS band descriptor expectations (Taylor & Wigglesworth, 2009). The reduction in cohesion and coherence errors appears to stem from explicit, example-driven feedback provided by AI tools. Students' shift from overusing basic connectors to employing a broader range of cohesive devices indicates a deeper understanding of how these elements function in academic writing. This outcome shares similarities with Crossley et al. (2016), who argued that effective feedback on cohesion requires not merely pointing out errors but modeling alternative cohesive strategies, something generative AI was particularly skilled at delivering.

The questionnaire results further underscore the growing prevalence of AI tools in language learning, with most of the students reporting frequent use of such technologies to study English. This reflects a broader shift toward technology-driven learning methodologies. Students primarily used ChatGPT to detect and revise inappropriate linking errors and to find suitable collocations. In addition, some writing aspects, including linking ideas, organizing paragraph structure and better logical flow, have been reported to improve significantly by students. These improvements align with the findings of Sekewael and Anaktototy (2024) which advocate that feedback from ChatGPT can bolster coherence and cohesion in writing. One prominent merit of ChatGPT pointed out by the students is rapid response time, which is perceived as less time-consuming compared to traditional feedback methods from teachers or peers. Regarding future use, the majority of students expressed a positive intention to continue using ChatGPT as a scaffolding tool. However, some concerns were still raised about the accuracy of the feedback provided, with 14.3% of respondents expressing skepticism. This posits that the limitation of AI tools must be underscored and that students must apply critical thinking when engaging with AI feedback to ensure its relevance and reliability.

Even though the relevance and usefulness of ChatGPT affirms its role as a supplementary tool, the lower ratings concerning the independence of ChatGPT's feedback indicate that students still see traditional instruction and peer feedback as essential components of their learning journey. This suggests that while AI can enhance writing skills, it should complement rather than replace existing pedagogical practices.

6. Conclusion

This study sets out to examine the potential of generative AI feedback in enhancing coherence and cohesion in IELTS writing, a domain where candidates often struggle due to limited awareness of textual organization and logical flow. By investigating learners' engagement with AI-mediated feedback, the research provides valuable insights into how emerging technologies can augment traditional pedagogical practices in high-stakes second language (L2) writing contexts.

One of the central findings is that generative AI feedback, when applied thoughtfully, can support learners in addressing weaknesses in textual cohesion and overall logical structure. Unlike traditional forms of corrective feedback, which often focus on grammar, vocabulary, and surface-level errors (Ferris, 2010; Bitchener & Ferris, 2012), generative AI has the capacity to draw learners' attention to discourse-level issues, including transitions, thematic progression, and paragraph unity. This aligns with Hyland's (2005) assertion that successful academic writing requires more than accurate grammar; it requires the ability to construct coherent arguments and manage reader expectations effectively.

The findings also indicate that generative AI feedback fosters learner autonomy by providing immediate, individualised, and non-judgmental suggestions. Previous studies on automated writing evaluation (AWE) systems such as Grammarly (Dizon & Gayed, 2024) stressed the benefits of timely feedback, but these systems were often limited to fixed error

categories. In contrast, generative AI tools can simulate dialogic interaction and contextualise feedback within learners' specific writing tasks (Asadi et al., 2025). This adaptability allows learners to revise more strategically, thereby engaging in deeper processing of writing practices.

However, the integration of generative AI feedback is not without limitations. While learners benefited from guidance on coherence and cohesion, challenges arose in terms of overreliance and the potential for learners to adopt AI-generated suggestions uncritically. This concern resonates with broader debates in applied linguistics regarding the balance between scaffolding and learner agency (Ushioda, 2020; Warschauer & Liaw, 2011). Educators must therefore frame AI tools as complements, not substitutes, for critical engagement with writing. This highlights the importance of teacher mediation in helping students interpret and evaluate AI-generated feedback.

Future research should expand on these findings by examining the long-term effects of AI-assisted practice on IELTS Writing Task 2 performance, particularly whether improvements in coherence and cohesion transfer to other academic or professional writing contexts. In addition, it is important to investigate ethical considerations, such as the potential risk of standardising or synthesising learners' writing styles. Combining generative AI feedback with explicit writing instruction and peer collaboration may offer a balanced and effective approach to enhancing learners' writing development.

Hoàng Ngọc Quỳnh Như is an English language lecturer at the Industrial University of Ho Chi Minh City, Vietnam. She holds an MEd in TESOL from Edith Cowan University. She specialises in developing students' speaking, writing, listening, and reading skills. Her research focuses on applying Al-based tools to enhance English proficiency among university students, exploring attitudes and practical solutions. She has also conducted studies on pedagogical strategies, language assessment, collaborative learning, and the use of technology in teacher education.

Co- Trần Sĩ Nguyên Sa is a visiting lecturer in English at HCMC University of Technology, Vietnam. She holds an MEd in TESOL Presenters' from Edith Cowan University. She focuses on improving students' proficiency in speaking, writing, listening, and reading. Her research interests include Al applications in language education, digital literacy, and the sociocultural impact of technology on language teaching and learning. She also explores innovative pedagogical strategies and the role of technology in teacher training and curriculum development.

#27 Evaluating the Impact of Vocabulary Learning through Online Websites and Digital Resources on University EFL Students: Teachers' Perspectives

Nguyễn Thuỷ Hương[1]

Abstract

The rapid growth of digital technology has transformed teaching vocabulary in English as a Foreign Language (EFL), university students have begun employing online resources to study words on their own. In Vietnam, vocabulary websites, online dictionaries and interactive platforms provide learners a helpful substitute for classroom instruction for many learners. Teachers' perspectives on the educational usefulness of these tools are, however, not explored extensively. This investigation attempts to fill that gap by studying Vietnamese university EFL teachers' perceptions of the efficacy, advantages and limitations of internet vocabulary learning materials. With a convergent parallel mixed methods approach, quantitative data was obtained using questionnaires from 60 teachers; data were derived from 12 semi-structured interviews with academics. Descriptive and correlational analyses revealed macro-behavioural trends in general and thematic analysis investigated teachers' perceptions. Results showed that teachers regarded online resources to be supportive for increasing student vocabulary, independence and motivation. However, issues include inconsistent learning behavior, poor digital literacy, and poor self-regulation among students. The authors found that teachers have a pedagogical influence when implementing digital tools and monitoring students' progress and connection between online activities and curricular aims in a successful web learning scenario, in the end the effective use of technology in a web learning activity to students will not be possible without careful instruction and not with the use of technology alone.

Keywords: web-based vocabulary learning; EFL; teachers' perspectives; mixed-methods research; Vietnamese higher education

Tóm tắt

Sự phát triển nhanh chóng của công nghệ số đã làm thay đổi cách dạy và học từ vựng trong lĩnh vực học tiếng Anh như một ngoại ngữ (EFL), khi sinh viên đại học ngày càng sử dụng các nguồn tài nguyên trực tuyến để tự học từ vựng. Tại Việt Nam, các trang web học từ vựng, từ điển trực tuyến và các nền tảng tương tác trở thành những công cụ hỗ trợ hữu ích, giúp bổ sung cho việc học trên lớp. Tuy nhiên, quan điểm của giáo viên về giá trị sư phạm của những công cụ này vẫn chưa được nghiên cứu đầy đủ.

Nghiên cứu này nhằm lấp đầy khoảng trống đó bằng cách tìm hiểu nhận thức của giáo viên đại học tại Việt Nam dạy tiếng Anh như một ngoại ngữ về hiệu quả, lợi ích và hạn chế của các tài liệu học từ vựng trên Internet. Sử dụng phương pháp hỗn hợp song song hội tụ, dữ liệu định lượng được thu thập thông qua phỏng vấn với 60 giáo viên, trong khi dữ liệu định tính được thu thập từ 12 cuộc phỏng vấn bán cấu trúc. Phân tích mô tả, tương quan và phân tích chủ đề được áp dụng để khám phá xu hướng và quan điểm của giáo viên.

Kết quả cho thấy giáo viên đánh giá các nguồn trực tuyến giúp cải thiện vốn từ vựng, tính tự chủ và động lực học tập của sinh viên. Tuy nhiên, vẫn tồn tại các vấn đề như thói quen học tập thiếu nhất quán, kỹ năng số hạn chế và khả năng tự quản lý thấp. Nghiên cứu nhấn mạnh vai

[1] *University of Greenwich; Email: huongnt114@fe.edu.vn*

trò hướng dẫn sư phạm của giáo viên trong việc tích hợp công nghệ, theo dõi tiến độ và liên kết hoạt động trực tuyến với mục tiêu chương trình học, bởi việc sử dụng công nghệ chỉ thực sự hiệu quả khi có sự định hướng giảng dạy cẩn trọng.

Từ khóa: học từ vựng dựa trên web; EFL; quan điểm của giáo viên; nghiên cứu phương pháp hỗn hợp; giáo dục đại học Việt Nam.

1. Introduction

Knowledge of vocabulary is a vital component in second and foreign language development, which serves as the foundation for learners' understanding of input, accurate expression of ideas and the successful participation in academic and communicative tasks. In particular to university EFL contexts, students must deal with progressively more complex texts and discourse focused on the disciplines in which they find themselves, which places considerable demands on their lexical competence. As a result, the teaching field of vocabulary has emerged as one of the key challenges facing English language education, especially when classroom time is restricted and learner proficiency is varied. Vocabulary learning has been transformed by the recent advancements of digital technology, which are opening the door to online resources that extend learning beyond classroom walls. Multimodal input, interactive exercises, and opportunities for repeated exposure and retrieval are included in online platforms, vocabulary learning websites, and mobile-assisted apps that support learning. Research has empirically indicated that technology-enabled vocabulary learning contexts can lead to significant gains in vocabulary acquisition and retention compared to traditional practices (Zou et al., 2021; Şimşek & Şimşek, 2025). These benefits are generally linked to higher student engagement, the change from one pace of learning with a set vocabulary at different steps, and deeper lexical processing. However, pedagogical affordances have not ensured success of web-based vocabulary learning. However, there is increasing attention in studies that technology by itself does not cause learning to have meaningful consequences; it is mediated through pedagogic design, learner strategies, and instructional support (Ertmer & Ottenbreit-Leftwich, 2010). Teachers in particular are critical in determining which of the web resources are chosen, used and related to teaching, learning and evaluation. Teachers' attitudes towards technology, their understanding of digital technology competence, and the students' readiness to learn about technology have a bearing on the level and significance of technology integration in a language classroom. The use of web-based vocabulary resources has become more prevalent in EFL classrooms in Asia and in Vietnam in particular in recent years, and with the rising prominence of online, blended learning technologies. As learners turn more and more to online websites and Internet resources for independent vocabulary learning, however, not much is known about how teachers view the success and struggle of using these resources empirically. Most previous research has concentrated on learner outcomes, failing to explore teachers' perspectives, especially in higher education and context-specific settings like Vietnam ((Rahmani et al., 2022; Guo et al., 2022). To fill this gap, the current research seeks to investigate Vietnamese university EFL teachers' views on the impact of web-based vocabulary learning resources on students' vocabulary development. By investigating teachers' perceived benefits, difficulties and pedagogical issues, this investigation seeks to provide insights into ways in which web-based learning of vocabulary may be well incorporated in EFL teaching at tertiary level. In addition to filling an empirical void, this research contributes to research and practice on EFL vocabulary teaching from many angles. First is that it moves the emphasis of analysis from outcome-orientated to teachers as central mediators of web-based vocabulary learning, to the extent that it looks at how pedagogical beliefs and pedagogic choice influence the efficacy of digital resources. Second, the fact that this study uses a mixed-

methods design means that the study is both broad and deep, and it provides qualitative pedagogical perspectives to put quantitative trend in perspective. Third, the research adds context specific evidence of Vietnam, a rapidly developing EFL context with no published evidence internationally exploring digital vocabulary learning. Together, these contributions advance the current understanding of technology-enhanced vocabulary pedagogy and contribute to more contextually sensitive instructional practices.

2. Literature

2. 1. Theoretical Foundations of Web-Based Vocabulary Learning

Web-based vocabulary learning is theoretically based on several influential frameworks in applied linguistics and educational psychology. Theoretically, learning vocabulary is more effective when people are involved in processing the lexical items through multiple cognitive operations, including semantic elaboration, contextualization, and repeated retrieval (depth of processing theory). Such systems are often supported in digital vocabulary resources via multimodal input, interactive tasks, and spaced repetition mechanisms. Moreover, sociocultural theory highlights the mediating role of tools in learning, framing the usage of web-based platforms as mediational means that shape learners' interaction with their lexical knowledge. Online vocabulary environments enable learners to negotiate meaning, have access to authentic examples of vocabulary use, and receive immediate feedback, which is beneficial for the internalization of vocabulary knowledge. These theoretical perspectives collectively support the pedagogical potential of web-based vocabulary learning when it is meaningfully integrated into instructional contexts.

2.2. Vocabulary Learning Outcomes in Technology-Mediated Environments

An increasing number of empirical studies have examined vocabulary learning outcomes in technology-mediated settings. The meta-analysis suggests that technology-assisted vocabulary instruction produces significantly higher vocabulary gains than traditional strategies, with its impact in higher education contexts being most significant (Boulton & Cobb, 2017; Zou et al., 2021). This is due to greater exposure, learner control, and numerous opportunities to practice the material multiple times. Evidence from the field of digital reading environments also suggests that glossed texts, hyperlinked vocabulary, and interactive annotations are positively related to incidental and intentional acquisition of vocabulary. Those exposed to digitally enhanced texts have better vocabulary retention and form–meaning mapping compared to those learning with non-digital ones (Guo et al., 2022). More importantly, studies also show that the gains in vocabulary learning are even greater when students are explicitly instructed about digital resources and how to use them strategically.

2.3. Learner Autonomy and Self-Regulated Vocabulary Learning

Web-based vocabulary learning encourages learner autonomy and self-regulated learning to a large degree. Digital platforms help to set learning goals, manage learner progress and adjust learning strategies to suit varying individual learner needs. For instance, there are empirical findings showing that learners with greater self-regulated behavioural engagement using digital vocabulary tools experience more vocabulary growth and retention (Dornyei & Ryan, 2015; Guo et al., 2022). But technology access does not automatically lead to autonomy. However, without pedagogical scaffolding, researchers see that learners may resort to surface-level strategies (e.g., rote memorization of word lists), reducing the opportunities for long-term

vocabulary development. This finding confirms the importance of teacher guidance in cultivating effective self-regulated vocabulary learning behaviors in web-based environments.

2.4. Teachers' Roles in Mediating Web-Based Vocabulary Learning

Although learners engage with web-based vocabulary resources, teachers are key agents mediating the effectiveness of their pedagogy. Research on technology integration reveals that teachers' beliefs, technological competence, and instructional intentions underpin how digital tools are incorporated in classroom practice (Ertmer & Ottenbreit-Leftwich, 2010). In vocabulary instruction, teachers play an influencing role not only in tool selection but also in task design, learning objectives, and assessment alignment. Empirical research investigating teachers' perspectives shows that although educators recognize the motivational and instructional value of web-based vocabulary tools, teachers are concerned about monitoring learner engagement and maintaining depth of learning (Latip & Mahadi, 2021; Katemba, 2020). Of particular relevance to higher education settings are these issues, where independent learning is promoted and teacher monitoring is limited outside classroom settings.

2.5. Contextual Factors in Asian and Vietnamese EFL Settings

The effectiveness of web-based vocabulary learning has been significantly mediated by contextual factors in EFL contexts. Academic work performed in Asian settings underscores the contribution of institutional expectations, examination-oriented curricula, and technological infrastructure on teachers' willingness and competence in integrating digital tools (Hwang et al., 2008). Factors such as cultural beliefs about teachers' authority and learner independence also influence the use of web-based learning in pedagogical practices. Research on technology-enhanced language learning in Vietnam indicates that although teachers see growing pedagogical value in using digital resources, challenges related to training, workload, and curricular alignment still exist (Trinh et al., 2022). There is a notable dearth of studies systematically investigating teachers' views about web-based vocabulary learning using mixed-methods designs, indicating a clear gap for research in this context.

2.6. Synthesis and Research Gap

Taken together, the literature offers strong indicators regarding the impact of web-based vocabulary learning on lexical development, learner autonomy, and engagement in EFL settings. Several gaps remain, however. First, teachers' perspectives are relatively underreported compared to those of studies focused on learners. Second, there is a paucity of literature in the field of web-based vocabulary learning in Vietnamese institutions of higher education using robust mixed-methods designs. Lastly, how teachers' beliefs and pedagogical practices interact with perceived learning outcomes should be further examined. Filling these gaps is also important for advancing contextually responsive and pedagogically sound web-based vocabulary instruction.

Research Questions

Based on the reviewed literature, the study seeks to address the following research questions:

1. How do university EFL teachers in Vietnam perceive the effectiveness of web-based vocabulary learning resources for supporting students' vocabulary development?
2. What benefits and challenges do teachers identify in the implementation of web-based vocabulary learning resources in university EFL contexts?

3. How do teachers' perceptions influence their pedagogical practices and expectations regarding students' vocabulary learning outcomes?

3. Methodology

3.1. Research Design

Research questions were complemented with qualitative data; therefore, the study adopted a mixed-methods research design. A mixed-methods design was chosen because it allows for the integration of quantitative trends and qualitative insights in order to gain richer insights into teachers' perspectives concerning web-based vocabulary learning resources. More specifically, a convergent parallel design was used to collect quantitative and qualitative data simultaneously, analyze them independently, then integrate their data during interpretation. The quantitative part captured the overall patterns of teachers' beliefs for the effectiveness, benefits, and challenges of using web-based vocabulary learning resources (RQ1 and RQ2). The qualitative aspect aimed to obtain a broader insight to teachers' experiences and rationale for instruction such as their perceptions that shaped instruction and their expectations related to achieving student outcomes (RQ2 and RQ3).

3.2. Pedagogical Setting

The study was conducted within the Vietnamese higher education system, where English is taught as a foreign language and is used for both general and academic purposes. At the university level, English as a Foreign Language (EFL) education usually includes mandatory English courses for students who are not majoring in English, as well as specialized language courses for those who are majoring in English. Vocabulary learning is often integrated with reading, speaking, and writing classes, with less time dedicated solely to vocabulary development in class. In recent years, many universities in Vietnam have encouraged or subtly supported the use of web-based vocabulary learning tools, such as online dictionaries, vocabulary websites, spaced repetition applications, and mobile phone-enabled learning platforms. However, the extent to which these resources are integrated into teaching depends on individual teachers' pedagogical beliefs and technological skills.

3.3. Participants

Among EFL teachers at public and private universities in Vietnam, all participants had prior experience using or recommending web-based vocabulary learning resources in their teaching.

Table 1. Participant Demographic Information

Variable	Category	n	Percentage (%)
Gender	Female	38	63.3
	Male	22	36.7
Teaching Experience	1–5 years	15	25.0
	6–10 years	21	35.0
	Over 10 years	24	40.0
Academic Qualification	MA	44	73.3
	PhD	16	26.7
Teaching Context	English majors	27	45.0
	Non-English majors	33	55.0

In all, 60 teachers completed the questionnaire. Out of them, 12 teachers were purposively selected for follow-up semi-structured interviews in order to ensure diversity in teaching experience, institutional context, and frequency of technology use.

3.4. Instruments

3.4.1 Questionnaire

A structured questionnaire was developed to collect quantitative data on teachers' perceptions. The questionnaire consisted of three main sections aligned with the research questions:

Section A: Perceived effectiveness of web-based vocabulary learning resources (RQ1)

Section B: Perceived benefits and challenges of implementation (RQ2)

Section C: Pedagogical practices and expectations regarding student vocabulary outcomes (RQ3)

Items were measured using a five-point Likert scale ranging from 1 (Strongly disagree) to 5 (Strongly agree). The questionnaire was reviewed by two experts in EFL pedagogy to ensure content validity and clarity. A pilot study (n = 15) was conducted, resulting in a Cronbach's alpha coefficient of 0.87, indicating high internal consistency.

3.4.2 Semi-Structured Interviews

Semi-structured interviews were carried out in order to gather qualitative information and insights into teachers' experiences and beliefs. The interview structure consisted of open-ended questions on the:

Teachers' evaluations of students' vocabulary development through web-based resources

Observed changes in learner autonomy and engagement

Challenges in guiding and monitoring students' use of online tools

Pedagogical decision-making related to technology integration

Interviews lasted approximately 30–45 minutes and were audio-recorded with participants' consent.

3.5. Data Collection Procedures

Data were collected over a 12-week period. The questionnaire was distributed online via institutional email and professional teaching networks. Participation was voluntary, and anonymity was assured. Interviews were conducted after the questionnaire phase to allow preliminary quantitative findings to inform qualitative exploration. All interviews were transcribed verbatim for analysis.

3. 6. Data Analysis

3.6.1 Quantitative Data Analysis

Statistical software was used to analyze quantitative data. Descriptive statistics, including means, standard deviations, and frequencies, were computed to summarize teachers' perceptions.

Table 2. Teachers' Perceptions of Web-Based Vocabulary Learning Resources

Item	Mean	SD
Enhances students' vocabulary knowledge	4.21	0.63
Promotes learner autonomy	4.35	0.58
Increases student motivation	4.18	0.66
Requires structured teacher guidance	4.47	0.54
Difficult to monitor students' usage	3.89	0.71

Inferential analyses (e.g., correlation analysis) were conducted to examine relationships between teachers' perceptions and reported pedagogical practices (RQ3).

3.6.2 Qualitative Data Analysis

Qualitative data were analyzed using thematic analysis following an iterative coding process. Initial codes were generated from the interview transcripts and subsequently grouped into broader themes. To enhance reliability, a second coder independently reviewed a subset of transcripts, with discrepancies resolved through discussion.

Table 3. Summary of Qualitative Themes

Theme	Description
Perceived pedagogical value	Teachers' beliefs about vocabulary gains and learning efficiency
Learner autonomy and responsibility	Students' self-directed use of online resources
Instructional challenges	Monitoring, guidance, and time constraints
Teacher mediation	Strategies for scaffolding and aligning tools with curriculum

2.7. Integration of Quantitative and Qualitative Findings

Both sets of data were integrated during interpretation to address the research questions holistically. Quantitative results provided an overview of general perception trends, while qualitative insights explained underlying pedagogical reasoning and contextual constraints.

4. Results

4. 1. Quantitative Results

The quantitative analysis suggested that the perceptions held by Vietnamese university EFL teachers towards web-based vocabulary learning resources were relatively positive. According to Table 2, teachers agreed with each other that these resources contribute to students' vocabulary knowledge development (M = 4.21, SD = 0.63) and are supportive towards autonomy in learners (M = 4.35, SD = 0.58). The perceived enhancement regarding student motivation was also relatively high (M = 4.18, SD = 0.66), suggesting that web-based

tools were perceived by teachers as helpful affective and cognitive agents to support vocabulary learning. Interestingly, the item with the highest mean score is web-based vocabulary learning requiring structured teacher mediation (M = 4.47, SD = 0.54). This point indicates a considerable agreement among teachers that digital learning platforms are inadequate in themselves without pedagogical scaffolding. Teachers reported that monitoring students' independent usage of web-based resources (M = 3.89, SD = 0.71) was moderate, as they felt the teaching process posed challenges (as opposed to outright resistance). Correlation analysis then showed a significant positive correlation between teachers' perceptions of effectiveness and the frequency with which they reported integrating web-based vocabulary tools into instruction ($r = .42$, $p < .01$), suggesting that favorable beliefs were associated with greater pedagogical use.

2.2. Qualitative Results

Thematic analysis of interview data led to the conclusion that there were four general themes, which are summarized and elaborated in Table 3. First, in terms of perceived pedagogical value, teachers perceived observed growth in vocabulary range, especially in receptive knowledge and lexical recognition. Some of the participants reported confidence when encountering new vocabulary in reading and listening tasks. Second, the central tenet of learner autonomy and responsibility reinforced teachers' observations regarding the extent to which web-based resources prompted students to be take-charge of vocabulary learning. However, autonomy was typically noted to be uneven, with more proficient or motivated students experiencing more consistent benefits than lower-level learners. Third, instructional challenges were a recurring theme. Teachers worry about students' reliance on superficial learning strategies like memorizing single word meanings without meaningful context. Difficulty tracking students' real use of online tools outside of class was also often cited. Finally, the teacher mediation theme pointed out the importance of guiding. Teachers described implementing strategies, such as suggesting websites, assigning learning activities, and incorporating online vocabulary activities into assessments, to ensure purposeful use of web-based resources.

5. Discussion

5. 1. Teachers' Perceptions of Effectiveness (RQ1)

Results suggest that Vietnamese university EFL teachers generally perceive the use of web resources for vocabulary learning as facilitating students' vocabulary growth. The high mean values of vocabulary enrichment and learner empowerment correlate with previous literature indicating that digital tools offer flexible, learner-centered learning platforms for vocabulary. Crucially for us, the findings imply that not only are teachers aware of cognitive advantages, they also recognize motivational ones, and this supports that web-based resources are useful adjuncts to EFL instruction.

5.2. Perceived Benefits and Challenges (RQ2)

Although teachers saw a number of benefits, the results also suggest that there was a nuanced understanding of the challenges. Notably, teachers appeared to have not completely viewed web-based vocabulary learning as a fully self-sufficient method, with considerable consensus in favor of providing structured guidance. Rather, they see it as best suited to a pedagogical framework that supports strategic learning and contextualized use of vocabulary. The moderate level of difficulty reported for monitoring the usage of students is indicative of a common issue in technology-enhanced learning contexts, especially in higher education contexts where independent learning is emphasized. These findings indicate that these

challenges are not intrinsic to the digital technologies but arise due to instructional design, learner training, and accountability related problems.

5.3. Pedagogical Practices and Teacher Mediation (RQ3)

The positive relationship between teachers' beliefs and their instructional practice reflects the impact of teacher beliefs on classroom application. Teachers who perceived web-based vocabulary resources as advantageous were more likely to systematically incorporate them into instruction. The qualitative results also highlight the role of teacher mediation by suggesting that task design, support, and alignment with assessments can be used to scaffold student use of digital tools. This finding reinforces the argument that teachers remain central agents in technology-enhanced vocabulary learning. Rather than replacing traditional instruction, web-based resources function most effectively as pedagogically mediated supplements that extend learning opportunities beyond the classroom.

5.4. Implications for EFL Vocabulary Instruction in Vietnam

Collectively, the findings indicate that the effectiveness of web-based vocabulary learning resources in Vietnamese higher education depends largely on the pedagogical approach taken. Positive beliefs and perceived problems of teachers also indicate the requirement of professional development on digital pedagogy and vocabulary learning strategies. Institutional support, in the form of training and curriculum alignment, might enable the sustainable use of web-based vocabulary resources in EFL instruction.

6. Conclusion

Through a mixed-methods approach, this study explored how web-based vocabulary learning resources affected university EFL students in Vietnam from the teachers' perspectives by examining both broad perceptual trends and subtle pedagogical information. The research integrates quantitative questionnaire data with the interviews of Vietnamese EFL teachers to provide a robust understanding of how Vietnamese EFL teachers perceive both the pedagogical value and drawbacks of web-based vocabulary learning activities at institutions of higher education. As a result, the results show teachers perceive the potential use of web-based vocabulary resources with broadly positive attitudes. Teachers found these digital tools effective for helping learners develop new vocabulary in the area of increasing lexical knowledge, target language input, and opportunities to practice outside of the classroom (repeated practice). Web-based resources were also considered as promoting learner autonomy and fostering student motivation because of the control learners have over learning pace, material and learning methods. These impressions indicate an ability for web-based vocabulary education resource as a complement to in class instruction in promoting vocabulary skills into flexible and learner-focused settings. At the same time, the results show that there are common understandings among teachers that the practice of web-based vocabulary learning has no inherent self-regulation or pedagogic sufficiency in isolation. In fact, teachers repeatedly highlighted the importance of having guided instruction to support vocabulary learning that is meaningful and strategic and not in the form of rote memorization or an individualized approach to learning vocabulary. There are evident problems – such as tracking students' independent use of online resources, differences in the digital literacy and self-regulation skills of learners, or fluctuations in learning strategies – and those highlight the shortcomings of unguided, unorganized use of digital vocabulary tools. These shortcomings highlight that the success of web-based vocabulary learning depends on the pedagogics of framing and supporting these resources. Crucially, this research highlights the importance of teachers as intermediaries in technology-mediated vocabulary learning. We conclude that the beliefs,

expectations, and teaching practice of teachers are significant to the choice, integration, and congruence of web-based vocabulary resources with curricular aims. Instead of being seen as a displace to traditional vocabulary teaching methods, web-based resources were found to be effective when part of a coherent pedagogical framework (comprising explicit instructions, task design, and mapping on to assessment procedure) as well. These results emphasize that technology offers an enabling device whose utility is the result of sound pedagogical use. By emphasizing the teachers' point of view in a Vietnamese university educational setting, this paper has a significant implication on the research on technology-supported vocabulary acquisition in EFL contexts. It fills an important gap in research that has been mainly concerned with the impact a student's vocabulary production has, which has not focused enough on teachers' instructional reasoning and contextual constraints. Based on quantitative and qualitative evidence, the study provides contextually relevant insights into the opportunities and challenges posed by internet language learning in Vietnam. It contributes significantly both to current literature on learning and EFL and to research on potential for the use of online vocabulary materials in sustainable and effective pedagogical practices to support vocabulary learning of university students.

7. Education and implications

The implications of this study are notable, with substantial significance for EFL vocabulary instruction, teacher professional development, and institutional policy in higher education. First, use web-based vocabulary learning resources pedagogically rather than as stand-alone tools. Teachers are instructed to explicitly support students in choosing suitable online resources, effective vocabulary-learning strategies, and applying newly acquired vocabulary in relevant settings. Structured tasks, including guided online vocabulary activities and following up with applying the learning in class, can serve as an antidote to superficial learning. Second, the findings emphasize the necessity of teacher education on digital vocabulary instruction. More pedagogical professional learning should include but are not limited to technical development such as instructional design, learner scaffolding, and evaluation for web-based vocabulary learning. Improving teachers' digital pedagogical competence might result in more assured and effective incorporation of online resources. The third must be structured to support learner autonomy. Web-based resources can encourage individual learning, though this often requires a clear explanation and explicit teaching of how to use those tools strategically to achieve meaningful learning impact. It is expected that through metacognitive training and reflection students will develop better and more sustainable vocabulary learning behaviour. Lastly, at an institutional level, both curriculum architects and faculty should address how they connect web-based vocabulary learning to course objectives and assessment strategies. In some ways, the institutional support which includes the proposed tools and clear guidelines for use and access to reliable digital resources will be necessary to support more widespread and fair implementation to an extended range of teaching contexts. Ultimately, web-based vocabulary learning resources are shown to offer significant potential for improving EFL vocabulary instruction in Vietnamese tertiary education. But the effectiveness of the latter depends greatly on well-informed pedagogical integration, teacher continuing mediation, and institutional support. It is hoped that future research could further this line of inquiry by assessing longitudinal learning outcomes, student perspectives, and comparative instructional approaches from various educational contexts.

ABOUT THE AUTHOR

Ms. Nguyen Thuy Huong (M.A.) is a dedicated educator and researcher with over 15 years of pedagogical experience within the FPT Education organization. She currently serves as a lecturer at FPT University, Greenwich Vietnam. Holding a Master's degree in English Linguistics from Hanoi University, her academic expertise spans Social-Emotional Learning (SEL), AI applications in education, and linguistics. Ms. Huong is particularly passionate about bridging the "well-being gap" in secondary education. Her recent research focuses on the systematic integration of SEL frameworks to enhance student emotional resilience and academic engagement in modern classroom environments.

#29 English-Major Students' Perceptions of AI Tools for Academic Research: A Quantitative Case Study at a Vietnamese University

Tran Thanh Tu[1], Tran Nam Anh[2]

Abstract

Artificial intelligence (AI) tools have entered rapidly into university classrooms, yet little is known about how English-major students use them across the entire chain of academic research activities rather than for writing alone. This study examined perceptions and use of AI tools for academic research among 188 undergraduates at Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT), Vietnam. A cross-sectional survey, grounded in the Technology Acceptance Model (TAM), self-regulated learning (SRL) theory, and the TPACK framework, measured seven constructs: perceived usefulness, perceived ease of use, teacher's AI integration, self-regulated learning, AI dependence, ethical awareness, and AI usage behavior. Responses were analyzed with descriptive statistics, reliability analysis, and exploratory factor analysis (EFA). Students reported widespread adoption of AI tools, ChatGPT in particular, but used them mainly to search for information and generate ideas rather than to produce finished text. The factor structure suggests that students see technology perceptions, teacher guidance, and self-regulation as connected parts of the same learning experience, rather than as separate factors. The findings extend technology acceptance research to undergraduate research training and show how universities can bring AI into research instruction without weakening academic integrity.

Keywords: artificial intelligence, academic research, technology acceptance model (TAM), English-major students

1. Introduction

1.1. General Context

Artificial intelligence has changed how universities operate and how foreign languages are taught (Arif, 2025). Since its launch in November 2022, ChatGPT reached 100 million users within just two months, making it the fastest-growing consumer application in history (Heaven, 2023). Moreover, modern large language models can do much more than simply retrieve information. Generative AI tools are capable of producing well-structured academic content while offering immediate feedback on grammar and writing style (Kasneci et al., 2023). For EFL students, these capabilities are particularly useful because AI can offer personalized language support, including immediate feedback on writing and opportunities for low-anxiety speaking practice. Nevertheless, growing concerns suggest that dependence on AI may weaken the deep cognitive processing required for authentic language acquisition. The question facing language educators is therefore no longer whether students will use AI, but how they can be guided to use it in ways that enhance rather than replace authentic learning (Najmiah & Al-Anbari, 2025).

Despite the transformative potential of Genarative AI, the pace of adoption has far exceeded the establishment of adequate pedagogical and ethical standards (Alkhatib et al., 2026). UNESCO's Guidance for Generative AI in Education and Research (2023) stressed the need for educational institutions to validate Genarative AI systems on their ethical and

[1] *Department of English, Faculty of Foreign Languages, HUFLIT, Ho Chi Minh City, Vietnam*
[2] *Department of English, Faculty of Foreign Languages, HUFLIT, Ho Chi Minh City, Vietnam.*

pedagogical acceptability, yet noted that fewer than 10% of schools and universities worldwide had formal guidance on AI at the time of publication (Silva & Janes, 2023).

1.2. Recent Studies

1.2.1. International Context

Recent studies suggest that generative AI, particularly ChatGPT, is changing the way EFL students approach academic writing (Tanharat & Phootirat, 2025). Using a mixed-methods approach based on Sociocultural Theory (SCT), the authors investigated 50 senior English-major undergraduates in Thailand, finding that students primarily use ChatGPT as a mediational tool to self-regulate their writing process, specifically for paraphrasing, brainstorming, and enhancing coherence (Tanharat & Phootirat, 2025). However, the authors noted that students maintain a cautious, critical attitude toward ethical concerns such as plagiarism and the reliability of AI-generated information. Ultimately, the authors argued that while AI offers useful cognitive support, human feedback remains essential for developing advanced academic writing proficiency.

Experimental evidence indicates that students who used AI under teacher guidance achieved significantly better learning outcomes compared to those in traditional settings (Guan et al., 2025). Working with 66 high school students in China, the authors found that the experimental group using AI under teacher guidance scored significantly higher in reading, writing, and overall English proficiency than the control group taught in a conventional format. According to the authors, despite the acknowledged benefits of AI in facilitating task completion and generating ideas, the majority of students still preferred the presence of human teachers. These results suggest that teachers remain essential in providing emotional support and pedagogical guidance that AI cannot replace (Guan et al., 2025).

In the context of postgraduate education, Alghamdi & Madini (2026) explored the perceptions of Master of Arts in TESOL students regarding the use of QuillBot for academic writing and publishing. Through semi-structured interviews with 15 female students in Saudi Arabia and applying the Technology Acceptance Model (TAM), the study reveals that students highly appreciate QuillBot for enhancing grammatical accuracy, sentence variety, and paraphrasing skills (Alghamdi & Madini, 2026). Nevertheless, the authors reported that participants had serious reservations about the risk of semantic distortion, academic integrity issues, and the potential erosion of independent writing skills due to overreliance. Consequently, the authors recommended that AI tools should be integrated strictly as supplementary aids rather than primary writing instruments, with careful evaluation from users.

How ChatGPT can support a broad range of language skills was examined by Ahmed et al. (2025) in a mixed-methods study involving 100 students at the Virtual University in Pakistan. According to the authors, interactions with ChatGPT significantly improved students' vocabulary, grammar, writing, and reading comprehension within a short timeframe. Results suggest that AI creates a personalized and low-pressure learning environment with real-time feedback, which is particularly beneficial for language development (Ahmed et al., 2025). However, the authors also cautioned against technical limitations, such as occasional inaccuracies and the inherent absence of authentic human interaction, which remains a vital component of holistic language acquisition.

Exploring the psychological drivers of AI adoption, Wang et al. (2025) applied the Integrated Model of Technology Acceptance (IMTA) to investigate the motivations of 347 university students in China using ChatGPT for EFL learning. Findings indicate that intrinsic motivation plays a dominant role in shaping students' intention to continue using AI tools,

significantly overriding traditional extrinsic factors like perceived usefulness or ease of use. According to the authors, when students experience an engaging, human-like interaction with AI, they are more motivated to adopt it for various academic tasks, including speaking practice and writing enhancement (Wang et al., 2025). Despite this enthusiasm, the authors also noted students' self-awareness regarding the risks of over-dependence and AI hallucinations, advocating for the strategic and guided integration of AI in higher education.

1.2.2. Vietnamese Context

Studies conducted in Vietnam indicate that AI tools offer both significant benefits and notable challenges for EFL students (X. H. N. Thi et al., 2025). Employing a mixed-methods approach with 314 English-majored students, evidence indicates that tools such as ChatGPT and QuillBot are widely used across different stages of academic writing, particularly for complex assignments such as research papers and literature reviews (X. H. N. Thi et al., 2025). According to the authors, there is a positive correlation between the frequency of AI usage and perceived benefits, including improved grammatical accuracy, idea generation, and reduced writing anxiety. However, the authors also cautioned that students face risks such as overreliance, information inaccuracy, and plagiarism.

In a study based on the Technology Acceptance Model (TAM), Vo & Nguyen (2024) explored the perceptions of 369 English-majored students in Central Vietnam regarding ChatGPT. According to the authors, although students exhibited highly positive attitudes and found the tool easy to use, they maintained a largely neutral stance on its overall usefulness, specifically recognizing that AI provided little help for listening and speaking skills (Vo & Nguyen, 2024). In particular, the authors reported that students' class levels significantly influenced their perceptions, whereas gender did not create a significant difference. To adopt ChatGPT effectively, the authors advocated for the development of specific teaching strategies, careful monitoring, and maintaining a critical balance between AI assistance and human interaction in the language learning process.

Applying the Unified Theory of Acceptance and Use of Technology (UTAUT) framework, T. T. M. Thi (2025) investigated AI usage among 53 English majors at a public university in Ho Chi Minh City. According to the author, learners predominantly utilized generative AI for self-study and homework to check grammar and brainstorm ideas, rather than for direct translation (T. T. M. Thi, 2025). The author found high levels of technology acceptance across both male and female students, emphasizing that instructors' recommendations wielded a much more significant influence on students' intentions to use AI compared to peer suggestions. Nevertheless, the author also drew attention to serious concerns in the qualitative data regarding AI-generated misinformation, unnaturally overcomplicated expressions, and the risk of tech-overreliance diminishing learners' critical thinking and creativity.

1.3. Bibliometric Evidence for the Research Gap

Figure 1

Temporal Overlay Visualization of Keyword Co-occurrence in AI Research

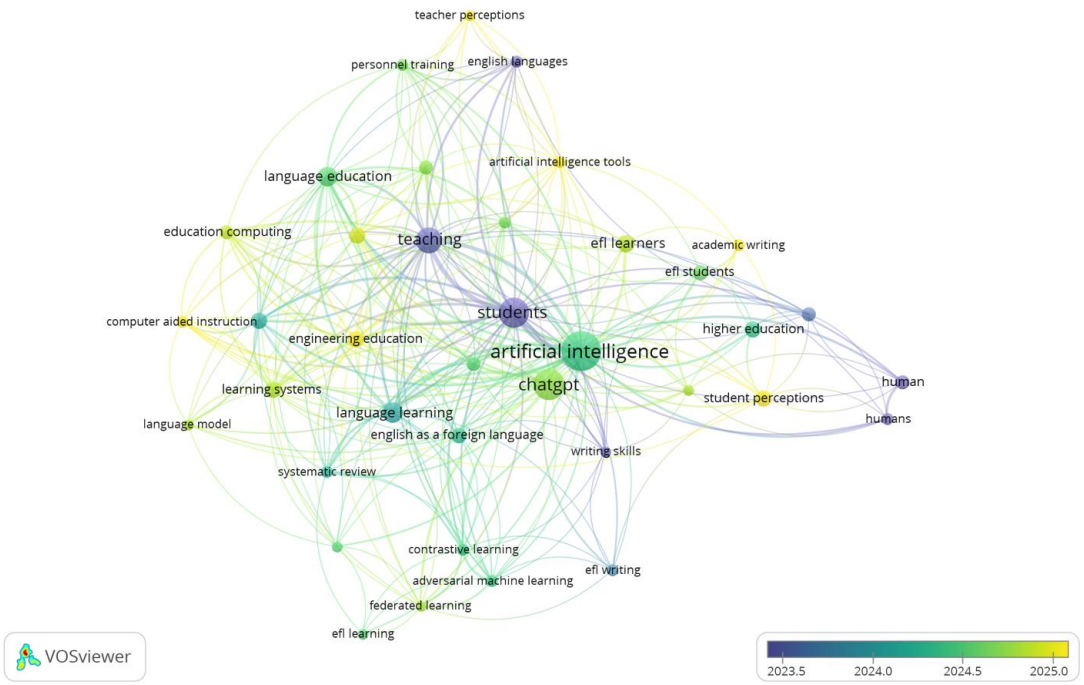

Table 1

Thematic Clusters Identified in the Bibliometric Analysis of AI Research in Language Education

Cluster	Main Theme	Keywords
Cluster 1	AI, ChatGPT & Student Perceptions in Higher Education	academic writing; artificial intelligence; chatgpt; efl learners; efl students; higher education; human; humans; motivation; structural equation modeling; student perceptions
Cluster 2	Language Learning, EFL Writing & Technology Acceptance	adversarial machine learning; contrastive learning; efl learning; efl writing; english as a foreign language; federated learning; language learning; systematic review; technology acceptance; writing skills
Cluster 3	AI in Education, Teaching & Teacher Perspectives	artificial intelligence in education; artificial intelligence tools; empirical studies; english languages; generative artificial intelligence; language education; personnel training; teacher perceptions; teaching

Cluster 4	E-learning Systems & Educational Technology Infrastructure	case studies; computer-aided instruction; e-learning; education computing; engineering education; language model; learning systems; students

The VOSviewer bibliometric analysis indicates that research on artificial intelligence (AI) in language education has developed rapidly and formed several clear research directions. The co-occurrence network identifies four main thematic clusters: (1) AI, ChatGPT, and student perceptions in higher education; (2) language learning, EFL writing, and technology acceptance; (3) AI in education, teaching practices, and teacher perceptions; and (4) e-learning systems and technology-enhanced learning environments.

The overlay visualization provides further insights into the temporal evolution of the field. Earlier research tends to focus on general concepts such as students, teaching, and writing skills, while more recent studies increasingly emphasize academic writing, student perceptions, teacher perceptions, and AI tools. This shift indicates a transition from general exploratory studies toward more focused investigations of user experience, pedagogical implications, and the practical integration of specific AI applications.

1.4. Research Gap and Significance of the Study

First, existing empirical research has largely focused on AI's role in supporting general language skills, particularly writing-related tasks such as grammar correction, paraphrasing, and idea generation (Ahmed et al., 2025; Tanharat & Phootirat, 2025; X. H. N. Thi et al., 2025). However, less attention has been given to how English-major students use AI tools for advanced academic research tasks, including developing research questions, designing methodologies, analyzing data, and synthesizing scholarly literature. This gap is also reflected in the bibliometric co-occurrence network, where keywords such as "academic writing," "writing skills," and "EFL writing" are highly visible, while terms related to research methodology and research skills are largely absent.

Second, the review of existing studies reveals a widespread use of descriptive, survey-based quantitative designs that examine general attitudes toward AI tools (Alharbi, 2024; Najmiah & Al-Anbari, 2025). In the Vietnamese context specifically, studies by Vo & Nguyen (2024) have applied established acceptance frameworks such as TAM and UTAUT to measure general perceptions. However, these studies have not fully considered pedagogical factors and students' self-regulation in AI-supported learning (Vo & Nguyen, 2024).

Third, Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT) presents a particularly significant site for such an investigation. As a university where English-major students are concurrently trained in linguistic competence and exposed to technology-enhanced learning environments, HUFLIT represents a demographic that heavily utilizes AI tools while being directly impacted by their influence on academic writing, linguistic feedback, and research practices.

1.5. Research Objectives and Questions

The first objective is to examine how English-major students at HUFLIT perceive the benefits and challenges of AI-supported academic research (Bui & Tong, 2025). The second objective is to evaluate the psychometric properties and underlying factor structure of the seven-construct measurement instrument. The third objective is to derive theoretically grounded and practically actionable implications from the empirical findings for the ethical

and effective integration of AI tools in English language education within Vietnamese higher education institutions.

To operationalize these objectives, the study addresses the following research questions:

RQ1: How do English-major students at HUFLIT perceive the benefits and challenges of AI-supported academic research, as measured through the constructs of Perceived Usefulness, Perceived Ease of Use, Teacher's AI Integration, Self-Regulated Learning, AI Dependence, Ethical Awareness, and AI Usage Behavior?

RQ2: To what extent do the seven theoretically hypothesized constructs demonstrate internal consistency and empirical distinctiveness, and what underlying factor structure emerges from exploratory factor analysis of the data?

RQ3: What are the theoretical and practical implications of the empirical findings for integrating AI tools ethically and effectively in English language education at Vietnamese higher education institutions?

2. Literature Review

2.1. The Paradigm Shift in AI-Mediated Language Education

In the domain of second language writing, generative AI tools have expanded their influence far beyond surface-level grammar correction to affect the conceptual content and structural organization of student work (Najmiah & Al-Anbari, 2025). generative AI has necessitated a fundamental redesign of how instructors approach the teaching and assessment of writing skills, as students now have access to tools that can produce polished academic prose with minimal human input (Kohnke et al., 2023). Beyond written production, learners increasingly perceive AI as a transformative tool for oral proficiency. For instance, studies in Vietnam indicate that students utilize generative AI platforms to improve their speaking skills through interactive, low-stakes practice that reduces performance anxiety and provides opportunities for sustained conversational engagement outside formal classroom settings.

2.2. Theoretical Perspectives on Technology Acceptance

2.2.1. Core Determinants within the TAM Framework

The Technology Acceptance Model (TAM), established by Davis (1989), remains the primary theoretical lens for evaluating user adoption of educational technologies. The model posits that two core constructs: perceived usefulness (PU) and perceived ease of use (PEOU), serve as the essential determinants of a user's behavioral intention to engage with new technology (Venkatesh & Davis, 2000). In the context of EFL education, perceived usefulness is typically operationalized as the belief that AI tools directly enhance linguistic proficiency, academic efficiency, and research productivity (Vo & Nguyen, 2024).

2.2.2. Expanding TAM in the Generative AI Era

In the context of ChatGPT adoption in higher education, studies utilizing the Unified Theory of Acceptance and Use of Technology (UTAUT) have shown that alongside performance expectancy, students' intention to use is significantly influenced by facilitating conditions and social influence. Furthermore, result demonstrability has been identified as an important predictor of learners' usage behavior. Additionally, students' decisions to accept AI are strongly driven by emotional factors as well as concerns about ethics, privacy, and academic integrity (Haetami & Aghata, 2025; Kohnke et al., 2023; Ravšelj et al., 2025).

2.3. AI Support and the Risk of Shortcut Learning in Self-Regulated Learning

Self-regulated learning (SRL), defined by Zimmerman (2002) as the self-initiated process through which learners set goals, monitor progress, and evaluate outcomes, has emerged as a critical construct for understanding how students engage with AI tools in educational settings (Zimmerman, 2002).

Generative AI offers significant potential as a scaffolding mechanism that supports the cyclical SRL process of forethought, performance, and self-reflection (Kasneci et al., 2023). AI-powered tools can provide personalized feedback, real-time progress monitoring, and metacognitive prompts that facilitate learners' self-regulatory development. For many English-major students in Vietnam, ChatGPT serves as a constant learning companion that supports autonomy through immediate writing feedback, research planning support, and self-directed vocabulary and grammar practice (Vo & Nguyen, 2024). Consistent with this view, recent systematic reviews indicate that Generative AI has strong potential to enhance SRL by helping students with goal-setting, strategy selection, and reflective evaluation across different academic contexts (Chiu, 2024; Kien, 2025; Ravšelj et al., 2025).

2.4. Ethical Integrity and Policy Realities

International frameworks from UNESCO (2023) and the OECD (2023) advocate for a human-centered and ethical approach to AI in education, emphasizing principles of transparency, accountability, inclusivity, and the protection of learner agency (OECD, 2023; UNESCO, 2023). However, a gap remains between these policy-level principles and classroom realities, particularly in developing countries where institutional resources, teacher training, and digital infrastructure may be insufficient. In Vietnamese higher education specifically, students frequently use AI tools, but their use is often not guided by clear institutional policies. While students recognize the utility of Generative AI for academic tasks, they also confront concerns over academic integrity, the reliability of AI-generated information, and the absence of clear boundaries regarding acceptable use (X. H. N. Thi et al., 2025).

3. Methodology

3.1. Research Design

A quantitative cross-sectional design was employed to examine students' perceptions of AI tools in academic research at Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT).

3.2. Participants and Sampling

The study involved 188 undergraduate English-major students at HUFLIT. Participants were selected using a convenience sampling approach, focusing on students with prior exposure to both language learning and research activities.

3.3. Instrument Development

The survey instrument consisted of two sections. The first section collected demographic information, including gender, year of study, prior experience with AI tools, frequency of AI use, most frequently used AI tool, and purposes of AI usage in academic research (multiple-response items). The second section comprised 27 Likert-scale items measured on a five-point scale (1 = Strongly Disagree to 5 = Strongly Agree), distributed across seven theoretically grounded constructs: Perceived Usefulness (PU, 4 items), Perceived Ease of Use (PEOU, 4 items), Teacher's AI Integration (TPACK, 5 items), Self-Regulated Learning

(SRL, 4 items), AI Dependence (AD, 3 items), Ethical Awareness (ETH, 3 items), and AI Usage Behavior (AUB, 4 items).

3.4. Data Collection Procedure

Data were collected during the second semester of the 2025–2026 academic year through paper survey and Google Forms.

3.5. Data Analysis

Data analysis was conducted using IBM SPSS Statistics (Version 26) and proceeded through three sequential phases, each corresponding to a specific research question.

4. Results

4.1. Descriptive Statistics

4.1.1. Demographic Characteristics of Respondents

The sample consisted of 188 undergraduate students. The sample was predominantly female (n = 140, 74.5%), with male participants comprising 25.5% (n = 48). The majority of respondents were third-year students (n = 158, 84.0%), while fourth-year students accounted for 16.0% (n = 30). A considerable proportion of respondents (96.8%, n = 182) reported having prior experience with AI tools for research purposes. In terms of frequency of use, 45.7% (n = 86) indicated using AI "often," followed by 26.6% (n = 50) who used it "very often" and 23.4% (n = 44) who used it "sometimes." ChatGPT was the most frequently used AI tool (70.2%, n = 132), followed by Grammarly (11.7%, n = 22), Google Translate (9.0%, n = 17), and Perplexity (9.0%, n = 17).

Table 2

Demographic Characteristics of Respondents (N = 188)

Variable	Category	n	%	Cum. %
Gender	Male	48	25.5	25.5
	Female	140	74.5	100.0
Year of Study	Third year	158	84.0	84.0
	Fourth year	30	16.0	100.0
AI Usage Experience	Yes	182	96.8	96.8
	No	6	3.2	100.0
Frequency of AI Use	Never	4	2.1	2.1
	Rarely	4	2.1	4.2
	Sometimes	44	23.4	27.6
	Often	86	45.7	73.3
	Very Often	50	26.6	99.9
Most Used AI Tool	ChatGPT	132	70.2	70.2
	Grammarly	22	11.7	81.9
	Google Translate	17	9.0	90.9
	Perplexity	17	9.0	99.9

4.1.2. Purposes of AI Usage in Scientific Research

Respondents reported multiple purposes for using AI in scientific research activities. The most prevalent purpose was searching for information (77.1%), followed by generating ideas and topics (72.9%), and translating academic content (61.7%). Writing or revising text and summarizing articles were reported by approximately 55% of respondents, while creating references or citations was the least common purpose (45.7%).

Table 3

Purposes of AI Usage in Scientific Research (N = 188, Multiple Responses)

Purpose	n (Yes)	% (Yes)	% (No)
Searching for information	145	77.1	22.9
Generating ideas / topics	137	72.9	27.1
Translating academic content	116	61.7	38.3
Writing or revising text	105	55.9	44.1
Summarizing articles	104	55.3	44.7
Creating references / citations	86	45.7	54.3

4.1.3. Descriptive Statistics of Likert-Scale Items

Table 4 presents the descriptive statistics for all 27 Likert-scale items across seven constructs. Overall, the mean scores ranged from 3.67 (AD1) to 4.26 (PU1), indicating that respondents generally expressed agreement to strong agreement with most survey items. The standard deviations ranged from 0.668 to 1.049, suggesting moderate variability in responses. All items exhibited negative skewness values, indicating a tendency toward higher scores.

Table 4

Descriptive Statistics of Likert-Scale Items (N = 188)

Item	M	SD	Skewness	Kurtosis	Min	Max
PU1	4.26	0.839	-1.280	2.232	1	5
PU2	4.24	0.823	-1.005	1.151	1	5
PU3	4.18	0.881	-0.968	0.742	1	5
PU4	4.22	0.878	-1.209	1.895	1	5
PEOU1	4.20	0.782	-0.915	1.429	1	5
PEOU2	4.19	0.757	-0.335	-1.185	3	5
PEOU3	4.04	0.892	-0.713	0.248	1	5
PEOU4	4.02	0.942	-0.741	0.201	1	5
TPACK1	4.05	0.861	-0.398	-0.614	1	5
TPACK2	4.05	0.876	-0.683	0.250	1	5
TPACK3	4.08	0.858	-0.667	0.273	1	5
TPACK4	4.10	0.870	-0.725	0.374	1	5
TPACK5	4.16	0.814	-0.662	0.010	1	5
SRL1	4.13	0.668	-0.258	-0.159	2	5

SRL2	4.09	0.801	-0.601	0.103	1	5
SRL3	4.16	0.841	-0.855	0.684	1	5
SRL4	4.14	0.852	-0.834	0.544	1	5
AD1	3.67	1.049	-0.849	5.515	1	5
AD2	3.93	0.946	-0.763	0.249	1	5
AD3	4.01	0.933	-0.894	0.616	1	5
ETH1	4.16	0.871	-0.866	0.413	1	5
ETH2	4.07	0.889	-0.651	-0.198	1	5
ETH3	4.10	0.897	-0.854	0.422	1	5
AUB1	4.12	0.873	-0.839	0.543	1	5
AUB2	4.13	0.847	-0.740	0.121	1	5
AUB3	4.11	0.874	-0.825	0.470	1	5
AUB4	4.01	0.903	-0.637	-0.020	1	5

One exception should be acknowledged. Item AD1 showed a kurtosis value of 5.515, exceeding the ±2 range commonly expected under strict univariate normality. This indicates that most responses were concentrated around the agreement categories, while a small number of students selected the lowest response options, creating a more peaked distribution with heavier tails. Such a pattern can occur in Likert-scale items that address sensitive self-perceptions, such as dependence (Blanca et al., 2013). Since the value was still below the |kurtosis| < 7 benchmark suggested by West et al. (1995), and because reliability analysis and exploratory factor analysis are relatively robust to moderate non-normality at this sample size, AD1 was retained without transformation.

4.2. Reliability Analysis

Cronbach's alpha coefficients ranged from .852 (AI Dependence) to .935 (Teacher's AI Integration), indicating good to excellent internal consistency across all seven constructs. All constructs met the established reliability thresholds (Nunnally, 1978). Moreover, all corrected item-total correlations (CITC) exceeded .30, and no item deletion would meaningfully improve the alpha values. These results support the retention of all items for subsequent analysis.

Table 5

Summary of Reliability Analysis by Construct

Construct	Items	Cronbach's α	CITC Range	Assessment
Perceived Usefulness (PU)	4	0.904	.757–.797	Excellent
Perceived Ease of Use (PEOU)	4	0.879	.723–.753	Good
Teacher's AI Integration (TPACK)	5	0.935	.814–.858	Excellent
Self-Regulated Learning (SRL)	4	0.892	.711–.790	Good
AI Dependence (AD)	3	0.852	.707–.795	Good
Ethical Awareness (ETH)	3	0.912	.800–.841	Excellent
AI Usage Behavior (AUB)	4	0.922	.777–.843	Excellent

Note. CITC = Corrected Item-Total Correlation. All CITC values > .30. Internal consistency thresholds follow the standard .70 reliability benchmark (Nunnally, 1978).

Table 6

Item-Level Reliability Statistics

Construct	Item	CITC	α if Deleted	Decision
Perceived Usefulness (PU)	PU1	0.797	0.872	Retain
	PU2	0.792	0.874	Retain
	PU3	0.757	0.886	Retain
	PU4	0.795	0.873	Retain
Perceived Ease of Use (PEOU)	PEOU1	0.753	0.840	Retain
	PEOU2	0.745	0.845	Retain
	PEOU3	0.752	0.839	Retain
	PEOU4	0.723	0.854	Retain
Teacher's AI Integration (TPACK)	TPACK1	0.814	0.923	Retain
	TPACK2	0.838	0.918	Retain
	TPACK3	0.819	0.922	Retain
	TPACK4	0.858	0.915	Retain
	TPACK5	0.814	0.923	Retain
Self-Regulated Learning (SRL)	SRL1	0.711	0.879	Retain
	SRL2	0.760	0.862	Retain
	SRL3	0.788	0.851	Retain
	SRL4	0.790	0.850	Retain
AI Dependence (AD)	AD1	0.707	0.847	Retain
	AD2	0.795	0.723	Retain
	AD3	0.748	0.784	Retain
Ethical Awareness (ETH)	ETH1	0.800	0.899	Retain
	ETH2	0.841	0.863	Retain
	ETH3	0.839	0.861	Retain
AI Usage Behavior (AUB)	AUB1	0.832	0.894	Retain
	AUB2	0.843	0.891	Retain
	AUB3	0.829	0.895	Retain
	AUB4	0.777	0.913	Retain

Note. CITC = Corrected Item-Total Correlation; α if Deleted = Cronbach's Alpha if Item Deleted. All items retained based on CITC > .30 criterion.

4.3. Exploratory Factor Analysis (EFA)

4.3.1. Sampling Adequacy and Sphericity

Prior to exploratory factor analysis, the suitability of the data was examined. The Kaiser-Meyer-Olkin (KMO) measure was .917, indicating high sampling adequacy. Bartlett's Test of Sphericity was statistically significant ($\chi^2 = 4672.900$, df = 351, $p < .001$), suggesting that the correlation matrix was appropriate for factor analysis.

Table 7

KMO and Bartlett's Test

Test	Statistic	Value
Kaiser-Meyer-Olkin Measure	—	.917
Bartlett's Test of Sphericity	Approx. χ^2	4672.900
	df	351
	Sig.	< .001

4.3.2. Total Variance Explained

Principal Component Analysis (PCA) with Varimax rotation was employed for factor extraction. Based on the eigenvalue-greater-than-one criterion, five components were extracted, collectively accounting for 75.127% of the total variance. The first component explained the largest proportion of variance (50.255% before rotation; 27.129% after rotation). After Varimax rotation, the variance was more evenly distributed across the five factors. The rotation converged in five iterations.

Table 8

Total Variance Explained

Comp.	Eigenvalue	% Variance	Cum. %	Rot. Total	Rot. % Var.	Rot. Cum. %
1	13.569	50.255	50.255	7.325	27.129	27.129
2	2.433	9.012	59.268	3.871	14.335	41.464
3	1.628	6.031	65.299	3.764	13.942	55.406
4	1.444	5.349	70.648	2.873	10.641	66.047
5	1.209	4.479	75.127	2.452	9.080	75.127

Note. Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization. Only components with eigenvalues ≥ 1.0 are shown.

4.3.3. Rotated Component Matrix

Table 9 displays the rotated component matrix using Varimax rotation with Kaiser normalization. Factor loadings below .40 are not reported for clarity. The five extracted factors demonstrated a clear structure. Factor 1 consisted of 13 items from PU, TPACK, and SRL, with loadings ranging from .543 to .826. Factor 2 included four PEOU items (.697–.811), Factor 3 included four AUB items (.800–.814), Factor 4 included three ETH items (.787–.864), and Factor 5 included three AD items (.864–.913). All items loaded clearly on their intended factors, with no problematic cross-loadings.

Table 9

Rotated Component Matrix (Varimax Rotation)

Item	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
SRL4	0.826				
SRL2	0.778				
PU1	0.775				
SRL3	0.755				
TPACK5	0.727				
TPACK4	0.700				
PU3	0.690				
PU2	0.678				
SRL1	0.652				
TPACK3	0.630				
PU4	0.626				
TPACK2	0.572				
TPACK1	0.543				
PEOU3		0.811			
PEOU1		0.716			
PEOU2		0.709			
PEOU4		0.697			
AUB2			0.814		
AUB4			0.807		
AUB3			0.802		
AUB1			0.800		
ETH2				0.864	
ETH3				0.809	
ETH1				0.787	
AD2					0.913
AD3					0.873
AD1					0.864

Note. Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization. Factor loadings < .40 are suppressed. Rotation converged in 5 iterations.

4.4. Summary of Key Findings

The quantitative analyses revealed several key findings. First, the descriptive statistics indicated that respondents generally viewed AI tools positively in the context of academic research. Mean scores for most Likert-scale items were consistently above 4.00, except for AI Dependence, which ranged from 3.67 to 4.01. Second, the reliability analysis confirmed strong internal consistency across all seven constructs, with Cronbach's alpha values ranging from .852 to .935. Third, the exploratory factor analysis extracted five factors, which together

explained 75.127% of the total variance. Although the study initially proposed a seven-construct structure, the empirical results reduced this structure to five factors. Factor 1 combined items from Perceived Usefulness, Teacher's AI Integration, and Self-Regulated Learning; Factor 2 retained all Perceived Ease of Use items; Factor 3 comprised all AI Usage Behavior items; Factor 4 grouped all Ethical Awareness items; and Factor 5 included all AI Dependence items.

5. Discussion

5.1. Student Perceptions of AI in Academic Research

The very high AI adoption rate among HUFLIT English-major students (96.8%) and their frequent use of AI are consistent with global trends, where AI adoption among university students has been reported at 80–92%. Students mainly used AI for information searching (77.1%) and idea generation (72.9%), rather than for producing complete texts. This suggests that AI functions primarily as a cognitive support tool during the exploratory stages of research, rather than as a tool for automating final outputs. Mean scores were above 4.00 across all constructs except AI Dependence (M = 3.67–4.01), indicating positive perceptions of AI, together with awareness of the risks of excessive reliance. This finding reflects the scaffolding–shortcut paradox identified in the literature (Alghamdi & Madini, 2026; T. T. M. Thi, 2025; Wang et al., 2025).

5.2. Factor Structure and Integrated AI Research Competence

The most important finding is the five-factor EFA structure departing from the hypothesized seven-construct model. While PEOU, AUB, Ethical Awareness, and AI Dependence were cleanly reproduced, PU, TPACK, and SRL converged into a single composite factor, Integrated AI Research Competence, suggesting students experience technology perceptions, pedagogical guidance, and metacognitive regulation as interrelated facets of a unified competence rather than separate dimensions. The clean separation of Ethical Awareness (loadings .787–.864) and AI Dependence (loadings .864–.913) as distinct factors suggests that ethical cognition and dependency perceptions may operate through different psychological mechanisms.

5.3. Implications

Theoretically, the Integrated AI Research Competence construct extends TAM by showing that PU, pedagogical scaffolding, and SRL may collapse into a single latent dimension when instructional integration is sufficiently strong. Future research should employ CFA and SEM to validate this construct across contexts.

Practically, AI competence programs should adopt holistic approaches developing technology perceptions, instructional guidance, and self-regulation concurrently through scaffolded research projects mirroring Zimmerman's (2002) SRL cycle. AI ethics should be embedded as a dedicated curricular component, not treated incidentally. Students should adopt deliberate strategies for evaluating AI outputs and periodically completing tasks without AI to mitigate dependency risks.

5.4. Limitations

Several limitations should be acknowledged. First, the study relied on a convenience sample from a single institution (HUFLIT), which limits the generalizability of the findings. Second, the use of self-report measures introduces the possibility of social desirability bias, particularly on sensitive items related to AI dependence and ethical awareness.

6. Conclusion

This study examined 188 undergraduate students' perceptions and use of AI tools in scientific research through a quantitative survey grounded in the TAM, self-regulated learning theory, and the TPACK framework across seven constructs. In general, the findings indicate that AI tools, particularly ChatGPT, have become widely integrated into students' research workflows (96.8% usage rate), mainly for information searching, idea generation, and translation, positioning AI as an augmentative rather than replacement resource. The measurement instrument showed strong reliability, with Cronbach's alpha values ranging from .852 to .935. While exploratory factor analysis produced a five-factor structure explaining 75.127% of total variance, departing from the hypothesized seven-construct model. The most important difference was that Perceived Usefulness, Teacher's AI Integration, and Self-Regulated Learning converged into a single composite factor termed Integrated AI Research Competence. This suggests that students see AI usefulness, teacher guidance, and self-regulation as closely connected parts of one broader competence.

Theoretically, this study extends the TAM to AI-assisted undergraduate research, introduces Integrated AI Research Competence as a novel composite construct, and provides evidence that ethical awareness and AI dependence function as empirically distinct factors, which may operate through different psychological mechanisms. Practically, the findings suggest that AI competence training should adopt a holistic approach simultaneously addressing perceived value, instructional scaffolding, and self-regulation rather than treating these dimensions in isolation. AI ethics should be integrated into formal research methodology courses instead of being presented as an additional topic. Students should also be encouraged to maintain critical autonomy by evaluating AI outputs carefully, checking them against primary sources, and occasionally completing tasks without AI assistance to preserve independent research skills.

#34 University Students' Attitude and Intentions Towards The Use of Chatgpt and Canva in a Project-based Learning Activity

Vi Le Bao[1]

Abstract

There is a growing interest in applications of Artificial Intelligence technology (AI) in education, especially in the English as a Foreign Language (EFL) environment, where user willingness and intentions play a significant role in successful AI integration. This study aimed to understand the attitudes and behavioral intentions of Business English students at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), Vietnam, regarding their use of AI tools (e.g., ChatGPT and Canva) in a project-based learning activity (PBL). 136 Business English students took part in a Likert scale survey which was constructed from the extended Technology Acceptance Model (TAM). The collected data was analyzed using Partial Least Square-Structural Equation Modelling (PLS-SEM) to assess the effects of self-efficacy (SE), creativity support tools (CSTs), perceived usefulness (PU), and perceived ease of use (PEOU) on students' attitudes (Att) and their behavioral intention (BI) toward future AI integration. The results found that Business English students demonstrated both positive attitudes and positive behavioral intentions towards AI technologies, which further highlighted the roles of self-efficacy and creativity support. The study also provided some implications and recommendations for adopting ChatGPT and Canva in higher education.

***Keywords*:** ChatGPT, Canva, Project-based Learning (PBL), Technology Acceptance Model (TAM), attitude, behavioral intention

1. Introduction

Artificial intelligence (AI) has gained public attention since its introduction in the 1950s. AI is defined as the capacity of several related technologies such as digital computers, or computer-controlled robots to execute tasks typically requiring human intelligence (O'Regan, 2016). The applications of AI technologies in education have been identified in various functions, including personalized learning, automated assessment, and administrative tasks (Eager & Brunton, 2023). This integration does not only present technological changes but also signifies a fundamental transformation in the dissemination, evaluation, and use of knowledge (O'Dea & O'Dea, 2023). The literature identifies at least ten ways in applying AI technology in education: (1) automatic grading system, (2) interval reminder, (3) teacher's feedback, (4) virtual teachers, (5) personalized learning, (6) adaptive learning, (7) augmented reality/virtual reality, (8) accurate reading, (9) intelligent campus and (10) distance learning (Yufeia et al., 2020). This transition has created opportunities for increased creativity and efficiency, fostering a more dynamic and interactive learning environment, while also posing challenges for educational institutions worldwide.

The recent release of ChatGPT (Generative Pre-trained Transformer) in 2022 by Open AI has accelerated digitalization and driven advancements in Generative Artificial Intelligence (GAI). According to Miller (2023), GAI comprises AI systems and algorithms which can synthesize realistic outputs and create new and novel contents such as text, images, audio,

[1] *Business English, Foreign Languges, Ho Chi Minh City University of Foreign Languages - Information Technology, Ho Chi Minh City, Vietnam; Email: vilb@huflit.edu.vn*

video, or code, in response to a designated prompt. This helps people to prototype ideas, generate content, or simulate interactive experiences. If ChatGPT, especially version 3.5, is classified as a text producing output of GAI, then image-producing outputs such as Canva, Bing Image Creator, DALL-E are examples of description-based imagery creation. Another significant type of GAI output concerns video production platforms like Runway or Pika Labs (Pika). These technologies can generate motion graphics from framed sequential images; however, they have demonstrated some limitations in producing smooth and coherent video content with free of charge access (Browning-Samoni, 2024).

In English as Foreign Language (EFL) educational contexts, AI tools or AI-driven platforms like ChatGPT or Canva have been extensively used by both educators and students. Recent studies primarily focus on the students' perspectives towards the use of AI tools in acquiring English language skills, including writing, speaking, and reading (Wong et al., 2013; Xiao & Zhi, 2023), whereas other research investigates EFL educators' attitudes toward the application of AI in their lesson preparation and assessments, such as developing lesson plans, creating multimedia presentations, and producing quizzes, or tests (Eager & Brunton, 2023) Notwithstanding its significance, there exists a noticeable lack of studies examining students' attitudes regarding the incorporation of such technologies in specialized university disciplines and in real-world academic tasks. Likewise, it had been observed that students in the author's Selling Skills course had been using tools like ChatGPT 3.5 and Canva to brainstorm and create product marketing postings on social media platforms (i.e. Facebook, Instagram, etc.) during their class projects. To be specific, groups of 5 or 6 students worked together to promote a product of their choice. They had to go through a few steps, including generating ideas, selecting suitable content, visualizing attractive images, designing compelling marketing banners or product templates. These marketing materials were then shared on social media platforms like Facebook or Instagram to advertise their products and to engage with potential customers. This hands-on project was part of the coursework assessment to learn how Business English students apply their knowledge and marketing theory into real-life practices. Acknowledging how these AI technologies could boost student creativity, support personalized learning experiences, and improve their study effectiveness, the author decided to explore Business English majored student' attitudes and intentions on the usage of AI tools in a project-based learning (PBL) activity.

Undoubtedly, a large number of theoretical frameworks have been proposed to unpack individuals' attitudes and intention to adopt a particular technology. Some of the most notable examples include the Technology Acceptance Model (TAM) (Davis, 1989), the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1980), and the Theory of Planned Behavior (TPB) (Ajzen, 1985). Among them, the Technology Acceptance Model (TAM) by Davis (1989) is widely recognized as a fundamental framework for understanding technology adoption (Wong et al., 2013). It has been extensively applied in various fields, contexts, and technological tools (Dishaw & Strong, 1999; Venkatesh & Bala, 2008; Wong et al., 2013; Shahzad et al.,2024). In this study, the Technology Acceptance Model (TAM) was utilized to gain an understanding of students' attitude towards the utilization of ChatGPT 3.5 and Canva, while also seeking for opportunities for their future application in PBL activities within the Vietnamese EFL context, such as social media-based product promotion. The research questions guiding this study are as follows:

1. What are students' attitudes toward the use of ChatGPT and Canva in PBL activities?
2. Are they going to use these tools for similar projects in the future?

2. Literature Review and Model Development

2.1. Project-based learning and AI incorporation

Project-based learning (PBL) represents a significant pedagogical shift in educational transformation, positioning students as active learners in their leaning journey. Contrast to traditional lecture-based, teacher-centered, and textbook-driven instructions, PBL enables students to apply their skills and knowledge, collaborate in groups, and synthesize various subject areas to address authentic, real-world problems (Campbell, 2014). Project-Based Learning (PBL) was grounded in constructivist theory by Hmelo-Silver (2004) and was initially introduced by John Dewey in the late 1890s (Simpson & Stack, 2010).The core of PBL lies in its emphasis on active and experiential learning, which requires students to form critical-thinking, self-reliance, responsibility, and discipline through the process of planning, organizing, managing their time, and self-motivating their progress (Thomas, 2000). Project-Based Learning (PBL) allows students to explore topics and questions independently, particularly during the language acquisition process. This approach also generates intentional opportunities for students to practice using the language and to focus on important language aspects like grammar, vocabulary, skills, and learning strategies (Stoller, 2006).

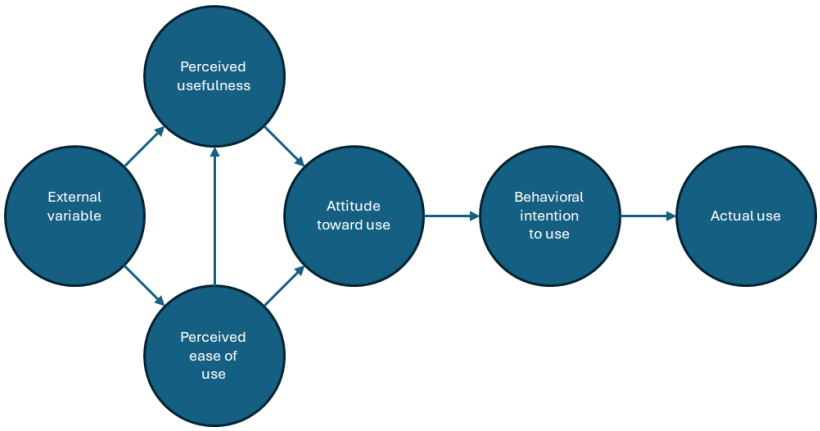
Given the development of AI technology and the rapid growth of the application fields, the combination of artificial intelligence (AI) technologies and project-based learning (PBL) is indeed an inevitable trend and a significant pedagogical approach (Tang et al., 2024). The incorporation of AI enables creativity and exploration for design, problem-solving, decision making, and investigation activities. The use of AI and machine learning (ML) in e learning platforms enhances student interest and retention. These technologies provide personalized feedback and tailored content, both of which are essential determinants to support active learning in project-based contexts (Gligorea et al. 2023). In addition, AI-driven tools such as ChatGPT enable learners to define their own learning outcomes and project topics, thereby fostering autonomy and personalized learning pathways. (Liang& Luo, 2024).

The potential of AI encompasses the development of EFL materials and complementary activities.In an AI-driven digital storytelling strategy, Belda-Medina and Goddard (2024) identified Canva.ai, Fliki, Invideo AI, Animoto, and Jasper A as useful tools for generating digital stories, videos, audio, and vocabulary worksheets. Meanwhile, Twee, Magic School, and Curipod were recommended to produce tasks, exercises, and assignments. These activities, in turn, support leaners' language development, creativity, and autonomy which reflects users' positive attitudes towards AI and its educational benefits in interactive, project-based tasks. Besides, collaborative technologies and AI- driven platforms provide ongoing assistance to students in their projects with peers and educators even beyond the confines of physical classrooms. These technologies not only enhance learners' productivity but also support teachers in tracking and monitoring students'progress more readily, hence providing intime feedback (Cheung & Vogel, 2013). Despite the benefits, it is important to acknowledge that the successful implementation of project work facilitated by digital technologies relies not only on technological access but also on users' digital literacy and their readiness for technology adoption, which remains as critical factors for effective implementation (Belda-Medina, 2021).

2.2 Chat GPT and Canva in EFL education

In EFL settings, ChatGPT presents many opportunities for improving language instructions and learning experiences. As mentioned by Yufeia et al. (2020), tools powered by AI like ChatGPT are effective learning companions, peer tutors, and virtual instructors. They can assist with reading and writing practices such as vocabulary enrichment, grammar check, and idea generation. ChatGPT provides personalized and adaptive feedback on text revision,

essay composition, content recommendation, and guidance on academic paper sections (Xiao & Zhi, 2023). For speaking, ChatGPT creates interactive environments where learners can build their confidence in expression, ease in discussions, and improvement in pronunciation (Monika & Suganthan, 2024). For PBL activities, Liang and Luo (2024) suggested using ChatGPT for business projects like "Exploring the Current Situation and Impact of Cashless Payments in Hong Kong". Students used ChatGPT to generate ideas and to formulate questionnaires for interviewing merchants and consumers. This was all meant toward fostering the development of language communication skills needed in professional environments, while concurrently building business-related vocabulary specific to the business world. In a similar manner, ChatGPT consists of a number of features that optimize the design process for projects like marketing promotional posts. Learners can come up with design ideas and content creation quickly and seamlessly, including ideas for captions; at the same time, they may dynamically explore the context in a way that fits with brand messaging and design constraints (Liu et al., 2025).



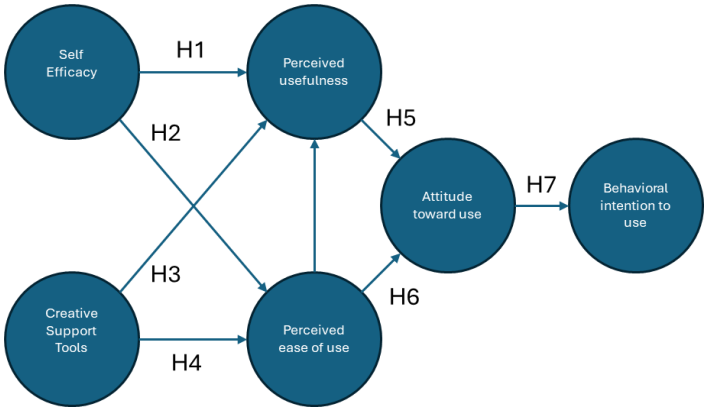
Meanwhile, Canva can be an excellent resource to integrate in EFL classrooms for promoting language skill acquisition, encouraging student involvement, and creating student-centered learning environments. Teachers can produce visual materials, vocabulary games, interactive exercises, and stories that suit students' diverse learning styles and proficiency levels (Emiliyana et al., 2024). In addition, students can create digital comics, visual essays, and presentations which helps strengthen their English communication skills and build confidence (Priyatna, 2023). Canva also promotes a collaborative leaning environment where students can post their co-created projects and receive feedback from fellow students and/or teachers, hence enhancing teamwork and communication abilities (Gehred, 2020). For example, teachers and students join projects via Canva's file-sharing feature to leave comments or assist with grammatical or spelling errors. As a web-based tool, Canva's accessibility and user-friendliness make it an exemplary tool for improving EFL learners' digital literacy and equipping them with essential expertise and creativity to work through the increasingly digitized world.

2.3 Technology Acceptance Model (TAM) and Hypothesis

Grounded in the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1980), Technology Acceptance Model (TAM)) aimed to apply the theory of belief-attitude intention-behavior relationship to the context of technology acceptance (Davis,1989). The model has also been extensively utilized as a paradigm for explaining users' technology adoption in educational contexts (Davis et al., 1989; Cheung & Vogel, 2013; Dhingra & Mudgal, 2019; Dahri et al., 2023). The model tries to identify ''the determinants of computer acceptance that are general, capable of explaining user behavior across a broad range of end-user computing technologies and user populations, while at the same time trying to be parsimonious and theoretically justified'' (Davis et al., p. 985). Therefore, the claimed determinants in TAM include individual's attitude (ATT), behavioral intention (BI), and actual use (AU) of a specific technology which are affected by two key factors known as perceived usefulness (PU) and perceived ease of use (PEOU).

Figure 1

TAM model (Davis, 1989)



Even though TAM is widely used, it has not been able to fully explain all the things that affect users' acceptance of technological systems because it does not clearly include antecedent or external variables that influence PEOU and PU (Dishaw & Strong, 1999). Davis (1989) also suggested that studies should investigate other factors that could affect PEOU, PU, and AU to enhance its explanatory power and applicability to a wider array of technology implementations in different contexts. Overtime, TAM has undergone several extensions and modifications by including external variables, such as social influence processes (i.e. perceived subjective norms, perceived organizational support), cognitive instrumental processes (i.e. output quality, job relevance, task-technology fit), system characteristics or system design features (i.e. perceived system quality, functionality), individual traits (personal innovativeness, self-efficacy, confidence), and organizational context (i.e. facilitating conditions, broader culture). For example, Dishaw and Strong (1999) proposed an extension of the TAM by integrating task characteristics and technology characteristics. The findings indicated that the new model provides more explanatory power than the original one in clarifying the reasons behind users' adoption of information technologies in task-oriented contexts.

Given the flexibility of the Technology Acceptance Model (TAM) (Davis, 1989) and the variability of specific external factors which can be incorporated within the TAM in different research contexts as well as different study objectives, the author would like to explore two external factors, including self-efficacy (SE) derived from Bandura's (1977) Social Cognitive Theory and creativity support tools (CSTs) based on Shneiderman's (2000) Creativity Support Tool framework. These factors are suitable considering the project's focus on self-guided use of AI tools and are anticipated to have significant impact on students' attitudes and behavioral intention (BI) in incorporating AI tools such as ChatGPT and Canva into their projects. Therefore, a new model was proposed as illustrated in figure 2, and the following factors are investigated in total:

(1) Self-efficacy (SE)
(2) Creativity support tools (CSTs)
(3) Perceived usefulness (PU)
(4) Perceived ease of use (PEOU)
(5) Attitude (Att) toward the AI use
(6) Behavioral intention (BI) for Actual use (AU)

Figure 2

Proposed Theoretical Framework

2.4 Self-efficacy (SE)

Self-efficacy (SE), according to Bandura (1977), is characterized as an individual's belief that one can effectively do the things that will lead to desired outcomes. This belief influences how they act, how hard they try, and how long it will last when coping with difficult situations. In the realm of technology, SE is regarded as significant factor that reflects an individual's self- assessment of their ability to accomplish a specific task by using technology (Compeau & Higgins, 1995; Teo, 2019). Many researchers have undertaken studies across different contexts, including educational institutions and professional settings, to demonstrate the substantial influence of self-efficacy on factors like Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) within the TAM. They found that individuals with high SE are more likely to see AI tools are useful and easy to use, hence increasing their propensity to utilize them (Venkatesh & Bala, 2008; Dahri et al., 2023). Considering the above impacts of SE on learners' AI tool adoption in their project-based tasks, the following hypotheses were set forth:

H1: SE has a positive effect on PU when employing ChatGPT and Canva.

H2: SE has a positive effect on PEOU when employing ChatGPT and Canva.

2.5 Creativity support tools (CSTs)

Unlike self-efficacy, which pertains to an individual's self- assessment of competence in applying AI tools, Shneiderman (2000)'s concept of creative support tools (CSTs) indicates the degree to which AI tools such as ChatGPT and Canva help individual express ideas creatively across diverse domains. Such technologies function not just as tools but as comprehensive platforms that automate routine tasks, improve efficiency, and promote innovative thinking (Secretan, 2011). CSTs do not hinder users' innovation; rather, they highlight the integration of human and machine contributions. Shneiderman (2000) argued that digital tools can scaffold creative work through various features like idea visualization, ideation prompts, reflection, rapid feedback, and design exploration, which might impact users' acceptance and effectiveness of technology. Even though the original model did not explicitly define PEOU or PU, the objectives of his framework as well as acknowledged challenges are intricately connected to the adoption and effective utilization of these tools by individuals. Simultaneously, concurrent research on extending TAM for Web 2.0 collaborative platforms has conceptualized system-level features such as compatibility, resources availability, and peer influence facilitations as external variables that significantly affect PEOU and indirectly PU.

This shapes users' attitudes, behavioral intentions, and actual use in project- based learning environments (Cheung & Vogel, 2013). Hence, the following hypotheses are proposed:

H3: Creativity support tools (CSTs) have a positive effect on Perceived Usefulness (PU).

H4: Creativity support tools (CSTs) have a positive effect on Perceived Ease of Use (PEOU).

2.6 Perceived usefulness (PU)

In the Technology Acceptance Model (TAM), Perceived Usefulness (PU) is considered as a crucial determinant to understand individual's overall attitude, defined as "the degree to which a person believes that using a particular technology would enhance his or her task performance" (Davis, 1989, p.320). It reflects the idea that users with higher willingness to use technology would attain favorable outcomes in accomplishing their goals or tasks such as improving performance, efficiency, and overall productivity. Numerous empirical research demonstrates the positive impacts of PU on users' attitude and behavioral intentions toward the adoption of new technologies (e.g., Davis et al., 1989; Dishaw & Strong, 1999) in educational contexts (e.g., Cheung & Vogel, 2013; Dahri et al., 2023). Therefore, it is probable that PU will result in students' positive perception of ChatGPT and Canva for their class projects.

H5: Perceived usefulness (PU) has a positive effect on students' attitude (Att) toward the use of ChatGPT and Canva.

2.7 Perceived ease of use (PEOU)

PEOU refers to "the degree to which a person believes that using a particular system would be free of effort" (Davis,1989, p.320). It is more likely to focus on the mental aspects, including cognitive resources and mental energy that people use when engaging with technology. In this study, PEOU means how easily Business English students can use and integrate ChatGPT and Canva into their project activities. Like PU, perceived ease of use (PEOU) is another key antecedent that shapes users' attitude towards a new technology. Consequently, PEOU drives their future intentions, which further manifest themselves in actual usage across various fields including education (Davis et al. 1989; Dhingra & Mudgal, 2019). Based on this, the following hypothesis is set forth:

H6: Perceived ease of use (PEOU) has a positive effect on students' attitude (Att) towards ChatGPT and Canva use

2.8 Attitude (Att) towards the AI use

The model includes attitude towards use (Att), which directs users' future behaviors toward AI tools. Attitude reflects the positive-negative evaluation, opinions, and sentiments with respect to performance of any technology, whereas it is theorized to mediate the effects of PEOU and PU on BI (Davis, 1989). Previous research by Wong et al. (2013) applied the TAM model to explore Malaysian student teachers' attitude toward computer implementation in classrooms. The findings supported that students' perceptions of usefulness (PU) and ease of use (PEOU) significantly affected their attitudes toward computer integration, which subsequently influenced their adoption intention towards learning activities. Shahzad et al. (2024) surveyed 320 Chinese university students and extended the TAM by including perceived intelligence to identify factors influencing students' intention to use ChatGPT. They found that perceived intelligence was a significant determinant in the adoption process and established a positive association between students' attitudes and behavioral intentions toward ChatGPT. These findings suggest that when students perceive Chat GPT as highly intelligent and capable of providing quality responses, their likelihood of using the tool increases. Based on these insights and the research objectives, Att towards AI use serves as a critical emotional factor that bridges cognitive appraisal, such as PEOU and PU, and behavioral intention (BI). The following hypothesis is therefore proposed:

H7: Students' attitude (Att) toward ChatGPT and Canva use has a positive effect on students' behavioral intention (BI) for actual use.

2.9 Behavioral intention (BI) for Actual use (AU)

To understand students' attitude towards using AI tools, the entire student adoption process cannot help but encompass covering behavioral intention (BI) for actual use (AU). Furthermore, due to its predictive design, the TAM includes BI as the factor of acceptance to predict actual technological use. Davis et al. (1989) asserts that BI reflects the degree to which an individual intends to use a particular system, serving as a strong determinant of AU behavior. Multiple studies have confirmed that learners' attitudes toward technology use significantly impact their BI and that a positive attitude may lead to greater commitment and use (Venkatesh & Davis, 2000). In the field of EFL, Coşkun and Solmaz (2024)'s study investigated the perceptions and attitudes of 650 high school English learners towards a mobile language learning application. They discovered that learners' intention to continue using mobile tools increases when they regard digital tools as important and advantageous for their various study goals, including for language practice (i.e., practicing, building English language abilities) and for project completion. Based on this foundation, the study investigates whether students' attitudes towards ChatGPT and Canva in their projects influence their BI to lead to actual use (AU) of these tools.

3. Methodology

3.1 Research design

The current study employed a quantitative methodology to investigate students' attitudes and behavioral intention regarding the use of ChatGPT 3.5 and Canva in a project-based learning activity, especially within a Selling Skills course at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). The online survey method was chosen to collect data due to its cost-effectiveness and time efficiency in regional distribution (Kurfali et al., 2017).

3.2 Sampling and data collection

The subjects of this study were third year university students majoring in Business English at HUFLIT. All participants were enrolled in the author's 12-week Selling Skills course, which was a compulsory EFL component of the university curriculum. Their English proficiency levels ranged from intermediate (B1) to upper-intermediate (B2) according to the Common European Framework of Reference for Languages (CEFR). The survey questionnaires were prepared in English and then distributed electronically via Google from which could be accessible from participants' personal devices. Initially, 150 students from three classes taught by the author were invited to participate in the survey at the end of the course in June 2025; however, only 136 of those students eventually answered the survey. Even though the results may have limited generalizability, it is convenient for a specific group of respondents and relevant to the items that are being measured (Shahzad et al., 2022). In terms of demographic information, there were 102 females (75 %), 31 males (22.79%), and 3 individuals (2.21%) who declined to disclose their gender. All participants are aged between 20 and 22 years and voluntarily consented to participate in the survey in compliance with institutional ethical standards.

3.3 Research Instrument

To investigate constructs associated with individuals' attitudes and behavioral intentions toward AI, particularly focusing on ChatGPT and Canva, participants were asked to provide responses to two essential demographic questions—gender and age—alongside twenty comprehensive scale items utilizing a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree): Self-efficacy (3 items) adapted from Murphy et al. (1989), creativity

support (4 items) adapted from Cherry, E., & Latulipe, C. (2014), perceived usefulness (3 items) adapted from Davis (1989) and Venkatesh et al. (2003), perceived ease of use (3 items) adapted from Davis (1989) and Venkatesh & Davis (2000), attitude (4 items) toward the AI use adapted from Davis (1989), Venkatesh et al., (2003), and Venkatesh & Davis (2000), and behavioral intention (3 items) adapted from Venkatesh et al., (2003), and Venkatesh et al., (2012). These items were derived from previously well researched studies which indicated a high degree of reliability. Table 1 below shows variables, statements, and sources of the items.

Table 1

Items used to measure TAM constructs

Factors	Items	Statements	Reference
Self-efficacy (SE)	SE1	I was confident in my ability to use different features of ChatGPT and Canva to complete my project tasks.	Murphy et al. (1989)
	SE2	I felt capable of solving problems I met while using ChatGPT and Canva during the project.	
	SE3	I was confident in learning how to use new features of ChatGPT and Canva on my own.	
Creativity support tools (CSTs)	CST1	The combination of ChatGPT and Canva in content generation and visual design helped to enhance my creativity during the project.	Cherry, E., & Latulipe, C. (2014)
	CST2	ChatGPT and Canva allowed me to come up with creative ideas for my project.	
	CST3	ChatGPT and Canva supported my team's collaboration, which generated highly creativity.	
	CST4	ChatGPT's and Canva's diverse features helped me produce creative designs and posts.	
Perceived Usefulness (PU)	PU1	Using ChatGPT and Canva saved my time on project tasks.	Davis (1989), and Venkatesh et al. (2003)
	PU2	ChatGPT and Canva helped to enhance the overall efficiency of my project.	
	PU3	ChatGPT and Canva helped me achieve better results in PBL activities.	
Perceived Ease of Use (PEOU)	PEOU1	I found it easy to navigate the interfaces of ChatGPT and Canva.	Davis (1989), and Venkatesh & Davis (2000)
	PEOU2	I could learn how to use ChatGPT and Canva for my project quicky.	
	PEOU3	It was clear and understandable to interact with ChatGPT and Canva.	
	Att1	I enjoyed integrating ChatGPT and Canva into my project.	Davis (1989), Venkatesh et al.,

Attitude to ChatGPT and Canva use (Att)	Att2	I believe using ChatGPT and Canva was a good idea for my project.	(2003), and Venkatesh & Davis (2000)
	Att3	ChatGPT and Canva are great for projects that involve collaboration.	
	Att4	I have a positive attitude toward ChatGPT and Canva use for similar projects.	
Behavioral Intention to use ChatGPT and Canva (BI)	BI1	I intend to use ChatGPT and Canva for any PBL assignments in the future.	Venkatesh et al., (2003), and Venkatesh et al., (2012)
	BI2	I would recommend ChatGPT and Canva to peers for project collaboration.	
	BI3	I plan to incorporate ChatGPT and Canva into my regular study routines	

4. Results and data analysis

After the data had been gathered online through Google forms and downloaded in a Microsoft Excel file in the .csv format, it was then integrated into the SmartPLS software version 3.0 for the purpose of statistical analysis. Partial Least Square-Structural Equation Modelling (PLS-SEM) was employed to investigate the conceptual model in three different areas: first, the measurement model, second, the structural mode, and third, hypothesis testing. According to Hair et al. (2017), PLS-SEM is a suitable technique for the investigation of complicated cause-effect structures, hence enhancing the comprehension of inter-relationships between observable and latent variables. It might also be utilized in research pertaining to acceptance and adoption. Therefore, the requisite steps must be undertaken to evaluate the reliability and validity of the construct, beginning with an assessment of the construct's internal consistency or reliability (outer loading coefficient, Cronbach's Alpha, CR), followed by an examination of the construct's convergent validity (AVE coefficient) and discriminant validity (Fornell-Larcker criteria). Subsequently, the linear structural model SEM should be analyzed using the variance inflation factor (VIF), R square value (R^2), path coefficient (β), communality, Cohen's f^2, Q^2 and SRMR. Finally, P value was employed to validate the proposed hypotheses (Hair et al., 2017).

4.1 Measurement model

The evaluation of the measurement model was validated through composite coefficients which are shown in Table 2 and are as follows:

Table 2
Summary of coefficients in the PLS-SEM model

Factors	Items	Factor Loading	Cronbach's Alpha	Composite Reliability (CR)	Average Variance Extracted (AVE)	VIF
Self-efficacy	SE1	0.919	0.914	0.946	0.854	2.977
	SE2	0.925				3.275
	SE3	0.927				3.289

Creativity support tools	CST1	0.906	0.855	0.903	0.699	3.168
	CST2	0.776				1.692
	CST3	0.822				1.913
	CST4	0.836				2.274
Perceived Usefulness	PU1	0.880	0.855	0.912	0.775	2.129
	PU2	0.862				1.989
	PU3	0.898				2.310
Perceived Ease of Use	PEOU1	0.899	0.861	0.915	0.783	2.432
	PEOU2	0.845				1.903
	PEOU3	0.909				2.500
Attitude to ChatGPT and Canva use	Att1	0.844	0.888	0.923	0.750	2.576
	Att2	0.922				3.794
	Att3	0.899				3.216
	Att4	0.794				1.717
Behavioral Intention to use ChatGPT and Canva	BI1	0.857	0.784	0.869	0.689	1.412
	BI2	0.822				1.873
	BI3	0.810				1.907

* Source: SmartPLS output

The reliability or consistency of a scale or questionnaire was initially evaluated using Cronbach's Alpha (CA). Hair et al. (2017) assert that a Cronbach's alpha (CA) value of 0.70 or above signifies good reliability, whereas values over 0.80 reflect qualified reliability. In table 2, all measured constructs return Cronbach's Alpha values of being greater than 0.70. Especially, the coefficients are as follows: Self-efficacy (0.914), Creativity Support Tools (0.855), Perceived Usefulness (0.855), Perceived Ease of Use (0.861), Attitude (0.888), and Behavioral Intention (0.784). Furthermore, the majority of item loadings on their associated factors are above 0.7, with the lowest being 0.776, representing strong relationships between items and their respective factors. These results confirm that the items within each construct are reliable and consistently measure the intended latent variables.

Likewise, the composite reliability (CR) scores were also examined since they provide a more precise measure of internal consistency than Cronbach's alpha by accounting for the differing reliabilities of distinct indicators through weighted loadings (Hair et al., 2017). The convergent reliability (CR) value for each construct was greater than 0.8, with values ranging from 0.869 (Behavioral Intention) to 0.946 (Self-efficacy). Accordingly, the values bring robustness and reliability to the measurement model, which supports the consistency of the constructs.

The constructs also showed notable convergent validity, as denoted through the Average Variance Extracted (AVE). This value must surpass 0.50 to demonstrate that each construct accounts for over half of the variance of their respective indicators (Hair et al., 2017). In this study, all of the component AVE values were greater than the required cut-off, varying between 0.689 (Behavioral Intention) and 0.854 (Self-efficacy), thereby confirming that the constructs sufficiently capture the variance of their respective indicators, thus affirming convergent validity within the measurement model.

Table 3 shows the discriminant validity of the constructs based on the Fornell–Larcker criterion. Hair et al. (2017) emphasized the importance of highlighting the diagonal values which reflects the square root of the Average Variance Extracted (AVE) for each construct. Especially, the square root of the AVE on the diagonal values should be higher than the off-diagonal values for each pair. In this case, Attitude (0.866), Behavioral Intention (0.830), Creativity Support Tools (0.836), Perceived Ease of Use (0.885), Perceived Usefulness (0.888), and Self-efficacy (0.924) consistently surpass their respective inter-construct correlations in the rows and columns. This evidence confirms that the discriminant validity of the constructs is achieved, ensuring the factors are empirically distinct from one another.

Table 3

Discriminant validity

	Att	BI	CSTs	PEOU	PU	SE
Att	**0.866**					
BI	0.779	**0.830**				
CSTs	0.800	0.691	**0.836**			
PEOU	0.875	0.710	0.773	**0.885**		
PU	0.790	0.690	0.748	0.781	**0.880**	
SE	0.882	0.684	0.755	0.847	0.738	**0.924**

* Source: SmartPLS output

4.2 Structural Model

In PLS-SEM, the structural model represents proposed relationships between different variables (Hair et al., 2017). To detect potential multicollinearity across the constructs, the Variance Inflation Factor (VIF) is examined and should be between 0.20 and 5.00 (Hair et al. (2017), where values below 5 indicate that multicollinearity does not pose a serious problem. According to the measurement model results shown in table, all items have VIF values ranging between 1.412 and 3.794, which are within acceptable range.

Table 4 presents the analysis of the coefficient of determination (R^2), shedding light to the model's explanatory power. Adjusted R^2 values were taken into consideration since they measure the number of predictors of the model while providing a more cautious assessment of explanatory accuracy. In this study, the R2 adjusted value was 0.791 for Attitude and 0.755 for Perceived Ease of Use, both indicating strong explanatory power. Meanwhile, the adjusted R^2 value for Perceived Usefulness (0.623) and Behavioral Intention Adjusted (0.604) fall within the moderate range. Overall, the results confirm the strength and substantial predictive power of the aforementioned model, with Attitude (Att) and Perceived Ease of Use (PEOU) being well explained by their predictors, while Behavioral Intention (BI) and Perceived Usefulness (PU) are moderately explained.

Table 4

R and R^2 Validation

	R Square	R Square Adjusted	Results
Att	0.794	0.791	Strong
BI	0.607	0.604	Moderate
PEOU	0.759	0.755	Strong
PU	0.629	0.623	Moderate

* Source: SmartPLS output

For overall fit of the structural model (PLS–SEM), the Communality index was assessed. Hair et al. (2017) say that the Communality index is the same as AVE in the PLS model and that it should be more than 0.5 for the model to be declared fit. Table 2 shows that the structural model has AVE values higher than 0.5 for all of the factors.

The study further investigated Cohen (2013)'s effect size index (f2) to classify their influence into 3 groups: (1) small effect size with f^2 less than 0.1, (2) medium with f2 between 0.25 and 0.40, and (3) large effect size with f^2 greater than 0.4 . According to PLS results shown in table 7, practical significance of the relationship between variables in the model fell in two groups: H1, H3, H4, and H5 exhibit a small effect, while H2, H6, and H7 have a substantial effect with f^2 values over 0.4. In addition, Table 5 contains the values of the Q^2 coefficient, which represents the level of prediction accuracy of the structural model. In other words, these values help to explain how well the model predicts the observed values. According to the findings, Att (0.582) and PEOU (0.583) demonstrate high predictive relevance while PU (0.477) and BI (0.378) show medium relevance (Hair et al. 2017).

Table 5

Q^2 Coefficient Analysis Results

	Saturated Model	Estimated Model
SRMR	0.081	0.090
d_ULS	1.367	1.697
d_G	1.138	1.248
Chi-Square	701.037	740.065
NFI	0.741	0.726

* Source: SmartPLS output

An additional critical metric for evaluating the overall fit of the structural model in SEM is Standardized Root Mean Square Residua (SRMR). This measure is used to assess how well the observed data matches the predicted values of the model. In accordance with Hu and Bentler (1998)'s guide and the SRMR results in table 6, the proposed structural model in this study fell within the tentative acceptance range (SRMR <0.10). In general, this study has conclusively shown that the PLS model effectively aligns with the empirical data based on the outcomes analyzed above.

Table 6

Model Fit Summary

	SSO	SSE	Q^2 (=1-SSE/SSO)
Att	544.000	227.605	0.582
BI	408.000	253.676	0.378
CSTs	544.000	544.000	
PEOU	408.000	169.948	0.583
PU	408.000	213.523	0.477
SE	408.000	408.000	

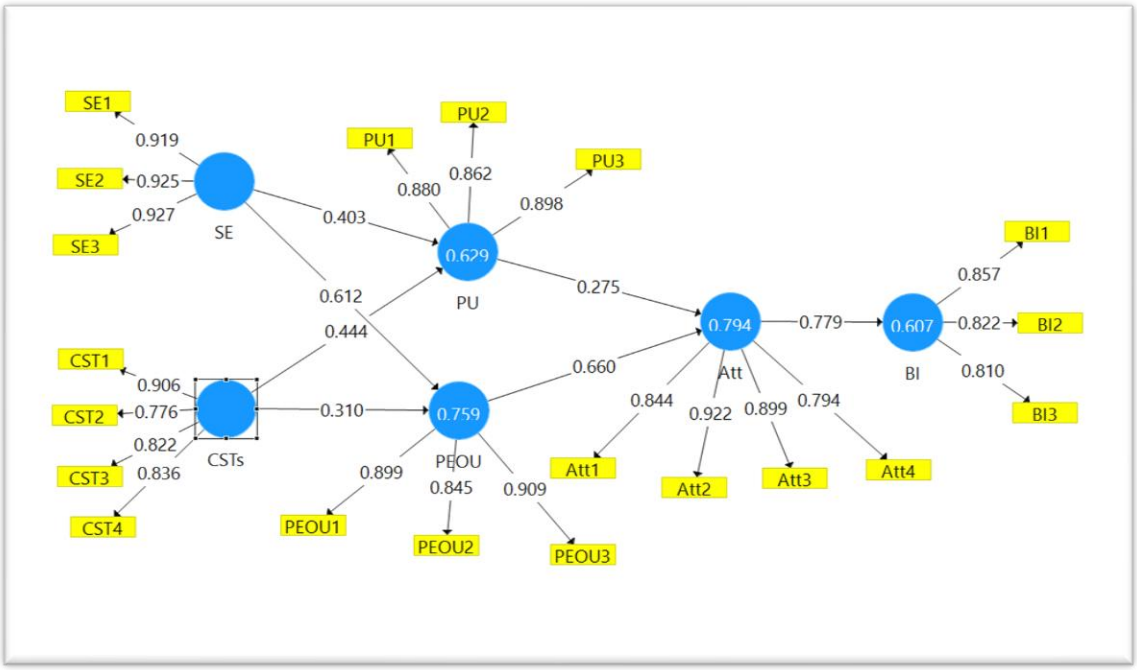
* Source: SmartPLS output

4.3 Hypotheses testing

To test the strength and direction of relationships between latent variables, path coefficients or standardized beta coefficients (β) were assessed, yielding values between 0 and 1 (Hair et al., 2017). The higher path coefficient (β) means a stronger relationship, while values closer to zero mean weaker effects. Through the results shown in table 7 and in figure 3, the strongest path was between Attitude and Behavioral Intention (β = 0.779), showing that students who have positive attitude towards the use of ChatGPT and Canva in their projects are more likely to intend to use such tools in the future. Among the factors influencing Attitude, PEOU showed a more significant impact with β of 0.660 in contrast to PU, which exhibited a β of 0.275. In relation to external factors, CSTs was found to have clear influences on both PU (β = 0.444) and PEOU (β = 0.310), while SE showed a more significant influence on PEOU (β = 0.612) than on PU (β = 0.403). This evidence suggests that PU and PEOU could mediate the effects of CSTs and SE on students' Att and BI regarding the use of ChatGPT and Canva in PBL.

The final phase was validating the hypotheses posited in this study by performing the bootstrapping method, with a repeated sample size of 5000 observations. Hypotheses were accepted only if the significance criterion of p-value < 0.05 was achieved (Hair et al., 2017). As shown in table 7, all seven tested hypotheses demonstrated significant relationships, with p-values substantially below 0.05; thereby, suggesting strong statistical support for the proposed paths.

Table 7



Results of Relationship Testing between Variables

Hypothesis	Relationship	Path coefficient	P-Value	f^2	Result
H1	SE→PU	0.403	0.000	0.188	**Accepted**
H2	SE→PEOU	0.612	0.000	0.668	**Accepted**
H3	CSTs→PU	0.444	0.000	0.228	**Accepted**
H4	CSTs→PEOU	0.310	0.000	0.172	**Accepted**
H5	PU→Att	0.275	0.004	0.144	**Accepted**
H6	PEOU→Att	0.660	0.000	0.826	**Accepted**
H7	Att→BI	0.779	0.000	1.545	**Accepted**

5. Discussion

This study utilized the Technology Acceptance Model (TAM) framework, incorporating two additional external factors (Students' Self-Efficacy and AI's Creative Support). The aim was to explore students' attitudes and their behavioral intentions after using ChatGPT and Canva to fulfil their project-based learning activities which were related to generating content and designing product promotion posts within a Marketing and Advertising course. Therefore, a conceptual model was proposed and statistically verified based on data collected from 136 Business English students at English Department of HUFLIT. The author used an online survey-based questionnaire technique to collect feedback on using the ChatGPT and Canva and distributed it to the intended audience. Followings are the remarkable results found from the investigation:

First, students' self-efficacy was found to have significant influence on both perceived usefulness ($\beta = 0.403$, $p = 0.000$) and perceived ease of use (PEOU) ($\beta = 0.612$, $p = 0.000$) of AI technologies in project-based learning (PBL) activities. This finding aligns with previous study of Venkatesh and Bala (2008), highlighting that students who perceive themselves as capable and confident in using digital tools are more likely to consider ChatGPT and Canva both useful and easy to use. In addition, when students believe they can use AI and design tools, they are more inclined to regard AI beneficial for enhancing creativity, productivity, and learning outcomes, so substantially shape students' attitudes and future intentions (Dahri et al.,2023). In other words, PU and PEOU help to mediate the relationship between students' self-efficacy and their attitude.

Similarly, CSTs demonstrated as a significant determinant of PU and PEOU, displaying $\beta = 0.444$, $p = 0.000$ and $\beta = 0.310$, $p = 0.000$, respectively. Within the scope of the study, Business English students were tasked with creating product promotion posts on social media platforms like Facebook or Instagram, AI tools such as ChatGPT and Canva provided a variety of features and resources to enhance their creativity. For example, ChatGPT may help with idea generation and brainstorming slogan or contents for social media postings. Meanwhile, Canva offers pre-designed templates, images, layouts, and other components for the creation of visuals. These platforms also include collaborative features through which students can

flexibly work, share, co-create, give feedback, and revise collectively (Andriyanto et al., 2021; Gehred, 2020). This somehow reflects the growing importance of such creativity support tools in educational settings, particularly for project-based learning, where innovation and creative problem-solving are highly valued. Hence, this evidence is in line with Shneiderman (2000) and Cheung and Vogel (2013)' s research, indicating that tools designed to foster creativity enhance users' perceived utility and usability.

In the extended TAM proposed by the author, perceived usefulness (PU) and perceived ease of use (PEOU) were dependent variables, influenced by two external factors: self-efficacy (SE) and creativity support (CS). In TAM, both PU and PEOU were essential indicators of predicting students' attitudes towards using ChatGPT and Canva. To be specific, PU had a significant positive effect on students' attitudes ($\beta = 0.275$, $p = 0.004$), indicating that when students perceive the usefulness of using AI tools such as ChatGPT and Canva for tasks like project and assignment completion, their favorable attitudes towards these tools are subsequently amplified. This outcome corresponds with previous studies on the implementation of the original TAM model (Davis, 1989; Cheung & Vogel, 2013). Simultaneously, PEOU exhibited a more notable impact on attitudes ($\beta = 0.660$, $p = 0.000$), suggesting that students prioritize the simplicity and usability of the tools when forming their overall impression. This result is also consistent with results of Davis et al. (1989) and Dishaw and Strong (1999) who highlighted the fact that PEOU is more critical than PU for AI tools integration. Generally, even though students value usefulness, the ease of using ChatGPT and Canva has a greater impact on forming positive attitudes. This phenomenon can be due to the relatively new integration of AI tools in education, where user-friendliness, such as Canva's drag-and-drop functionalities and ChatGPT's natural language interactions accelerates acceptance.

Finally, the results displayed a significant correlation between attitude and behavioral intention towards the use of ChatGPT and Canva ($\beta = 0.779$, $p = 0.000$), which is also the most substantial relationship within the model. The term "attitude" generally reflects students' self-evaluation and emotional disposition when engaging with AI tools. In the context of this study, students clearly showed favorable attitudes towards the use of ChatGPT and Canva in their project. Attitude is also regarded as the key factor in TAM which mediates the effect of PU and PEOU on students' behavioral intention to utilize AI technology. When students cultivate positive attitudes toward ChatGPT and Canva, there is a likelihood that they will continue to integrate these tools into their academic tasks and other future project-based learning activities. This confirms the findings of Wong et al. (2013), who found that positive attitudes directly drive the intention to use technology in higher education settings. Therefore, it is important to foster positive initial impressions and satisfaction among students as it will subsequently lead to sustained AI adoption behavior.

6. Conclusion and Implication

The purpose of this study was to explore university Business English students' attitudes and their behavioral intentions regarding the use of ChatGPT and Canva in a marketing project, as part of the coursework assessment. The author utilized a quantitative approach along with enhanced TAM as theorical framework to gather valuable insights. All variables and hypotheses have been examined and confirmed by PLS-SEM analysis, shedding light on their relevance and influence in the context of the targeted sample. A significant result found was students' positive attitudes towards the implication of AI tools for specific tasks, which in turn impact their behavioral intentions (Davis, 1989). The study also found that students value the functional benefits as well as the simplicity of integrating AI. Especially for social media product promotion projects, the combination of ChatGPT and Canva in content generation and

visual design features enabled students to ideate, design, and create professional-quality marketing content, thereby fostering engagement, skill development, creativity, and productivity. Furthermore, examining the two external factors, namely self-efficacy (SE) and creativity support (CSTs) contributed to better understanding the fundamental constructs of TAM and how they play a role in shaping students' attitudes and behavioral intentions.

The current study presents some practical insights for various stakeholders in educational institutions who seek to integrate AI and design tools into PBL activities. Given that students express positive attitudes towards AI tools, educators, institutions, and developers should nurture that advantage by providing sufficient support for effective AI implementation; at the same time, leveraging their potential impact on language education. This emphasizes the need of providing training sessions, guided tutorials, workshops, and structured project instructions to familiarize students with AI tools and build their confidence, which can enhance their perceived usefulness as well as perceived ease of use (Venkatesh & Bala, 2008; Dahri et al., 2023). Institutions should consider integrating AI tools into curricula by establishing explicit instructions for educators. This will enhance educators' confidence and motivation to apply AI tools in their classes, hence increasing student engagement with study and real-world activities. Additionally, the effectiveness of AI tools in the classroom can be further enriched if educators invest in designing learning environments that are authentic, collaborative, and creative. Educators should consider numerous factors when formulating pedagogically effective methodologies. This includes not only technical and ethical dimensions of these tools but also pedagogical aspects such as learning objectives, instructional strategies, and their roles as facilitators to optimize the usefulness of AI. These proposed implications align with the contemporary educational landscape, emphasizing the importance of technology, particularly AI tools, in facilitating language acquisition across various learning settings.

7. Limitation and Future Research

This study, like any research, was not without its limitations. Firstly, the data was collected from a specific student population, thus constraining the generalizability of the findings. This is due to the nature of the investigation's concentration solely on Business English students for project assignments within the author's Advertising and Marketing course. Researchers are advised to further investigate students' attitudes and behavioral intentions by expanding larger, and more randomized samples from various classes, faculties and institutions. This can also be implemented in other educational disciplines, including course subjects, PBL tasks, or assignments through collaboration with other instructors. Secondly, the study mainly focused on two typical tools – ChatGPT and Canva- which may not reflect the comprehensive landscape of emerging AI tools, especially in educational settings. Therefore, there should be more research looking into the integration of alternative technologies as well as their impact on user acceptance. Third, the present study made use of quantitative approach, utilizing self-reported measures which may introduce response bias or inaccuracies. Future research should incorporate mixed techniques with interviews or focus groups to achieve more objective assessments as well as to gain a more profound knowledge of users' opinions, their potential implementation challenges, and their expectations. A comparative study is recommended to examine the distinct implementations of AI-driven and traditional project-based learning tools in EFL classes. Lastly, regarding the proposed model incorporating two external variables—self-efficacy and creative support—research findings revealed that most of variables had direct and indirect correlations with Attitude and Behavioral Intention. Therefore, future studies should incorporate additional variables related to project-based learning activities, such as AI experiences and collaboration skills, while recontextualizing them within the Technology Acceptance Model to clarify their roles more distinctly.

She has participated in various academic and professional development activities and is committed to enhancing students' language competence and career readiness.

#40 INVESTIGATING ENGLISH-MAJOR UNDERGRADUATES' READINESS FOR AI-SUPPORTED ACADEMIC WRITING: A MULTIDIMENSIONAL PERSPECTIVE

Tran Phuong Anh [1], & Ngo Thi Thu Hien[2]

Abstract

The integration of Artificial Intelligence (AI) tools in academic writing has expanded rapidly, bringing both opportunities and challenges to the field of teaching English as a foreign language (EFL). Although the use of AI has become increasingly common among Vietnamese university students, empirical research on how English majors are prepared to engage with AI in academic writing remains limited. To address this gap, the present study adopts a mixed-methods approach to investigate English-major undergraduates' readiness and their intention to use AI-supported tools for academic writing, drawing on a multidimensional construct comprising (1) cognitive-metacognitive readiness, (2) linguistic readiness, (3) ethical and responsible awareness, and (4) technology readiness. A questionnaire survey was administered to 93 third-year English majors at Ho Chi Minh City University of Foreign Languages – Information Technology. Quantitative data were analyzed using descriptive statistics, correlation, and multiple regression. The results indicate that not all readiness dimensions significantly predict students' intention to use AI tools. In particular, technology enablers, a sub-dimension of technology readiness, emerged as the only significant predictor, while other dimensions played a less decisive role. In addition, semi-structured interviews were conducted to explore students' perceptions of AI-supported writing. Overall, the findings suggest that positive technological beliefs and supportive conditions outweigh perceived barriers in shaping intentions to use AI. The study contributes to TESOL research on AI-enhanced language learning and offers pedagogical implications for the responsible integration of AI tools in English academic writing instruction at Vietnamese universities.

Keywords: AI-supported academic writing; English-major undergraduates; multi-dimensional readiness; technology readiness; TESOL

1. Introduction

In recent years, artificial intelligence (AI) has improved many aspects of academic writing, including idea creation, content organization, literature synthesis, data management, editing, and ethical compliance (Khalifa & Albadawy, 2024). For English undergraduates who are required to learn and practise advanced writing skills, AI tools support them not only to produce academic texts but also to reduce human errors (Setiana & Chamalah, 2025).

According to Akanda and Talukder (2026), AI tools play a significant role in academic writing by providing immediate feedback on grammar, spelling and structure, which may help learners with their writing. However, many students are increasingly dependent on AI usage, which leads to a decline in their critical and independent thinking and writing abilities (Liu et al., 2023). In addition, there are challenges to academic integrity, such as plagiarism (De

[1] *Master of English Language Studies, Independent Researcher, Ho Chi Minh City, Vietnam; Email:phuonganh.tr1089@gmail.com*
[2] *Master of English Language Studies, Independent Researcher, Ho Chi Minh City, Vietnam; Email:friendship200561@gmail.com*

Angelis et al., 2023). Considering these advantages and disadvantages, it is essential to examine the readiness of university students to apply AI to assist in writing academic essays.

Although the use of AI in academic writing has attracted substantial literature, empirical studies that investigate AI-supported writing practices in the context of Vietnamese EFL higher education remain limited. Furthermore, existing studies on attitudes and AI usage have not been able to provide multidimensional frameworks for comprehending learner readiness in academic writing with AI tools. Recent studies mainly concentrate on a single aspect of AI application, such as the level of technological competence or perceptions (González-Torres et al., 2023; Rafida et al., 2024; Sustaningrum & Haldaka, 2025). However, there is a lack of studies examining readiness in relation to cognitive, metacognitive, linguistic, ethical, and technological factors.

This study investigates the readiness of English-major undergraduates to engage in AI-supported academic writing. It also aims to explore the interrelationship between various readiness elements, such as cognitive-metacognitive, linguistic, ethical, and technology readiness. Moreover, this study examines the predictive effects of these readiness factors on the intention of AI-supported writing tools among undergraduate English majors.

To successfully achieve the study's purposes, the following main research questions will be addressed:

RQ1. To what extent are English-major undergraduates ready for AI-supported academic writing in terms of cognitive-metacognitive, linguistic, ethical, and technological dimensions?

RQ2. What are the relationships between English-major undergraduates' intention to use AI tools for academic writing and their cognitive–metacognitive readiness, linguistic readiness, ethical and responsible awareness, and technology readiness?

RQ3. To what extent do cognitive–metacognitive readiness, linguistic readiness, ethical and responsible awareness, and technology readiness predict students' intention to use AI tools?

2. Literature Review

2.1. AI-Supported Academic Writing in EFL Contexts

Artificial intelligence (AI) integration into academic writing has grown rapidly in the English as a Foreign Language (EFL) settings. According to Jasim et al. (2024) and Thi et al. (2025), AI applications enhance grammatical accuracy, structural coherence, and learning engagement as well as reduce writing anxiety.

Despite these advantages, AI use in academic writing also raises concerns. Alarcón et al. (2025) highlighted the risk of over-reliance. Ethical issues, including privacy, discrimination, joblessness, and security threats, have also been reported (Huang et al., 2023). Furthermore, AI tools may produce inaccurate suggestions due to limited understanding of meaning and context (Ngo et al., 2024).

2.2. Learner Readiness

One of the factors that contributes to the effective use of educational technologies is learner readiness (Almziad, 2025), which is regarded as a multidimensional construct. This implies that effective technology use requires not only technical capability but also cognitive competence, self-regulation, and awareness of ethical considerations. This multidimensional

perspective enables a better idea of the way students interact with AI-supported academic writing.

2.3. Dimensions of Readiness for AI-Supported Academic Writing

2.3.1. Cognitive–Metacognitive Readiness

The cognitive-metacognitive readiness is a notion that explains the ability of students to effectively use AI-facilitated technologies in academic writing through the implementation of cognitive and self-regulation strategies (Yurt, 2025). According to self-regulated learning theories, cognitive-metacognitive preparedness governs the manner in which learners plan, monitor and evaluate AI-supported writing (Teng & Zhang, 2016; Zimmerman, 2002). Within the framework proposed by Teng and Zhang (2016), cognitive readiness is characterized as Text Processing and Course Memory, and metacognitive readiness as Idea Planning and Goal-oriented Monitoring and Evaluation. The AI usage in writing is controlled by cognitive-metacognitive readiness, but ethical or technology readiness may control the attitudes or access (Ng et al., 2024). In this way, students who are more cognitively-metacognitively prepared are likely to implement more purposeful, strategic, and ethical use of AI-assisted writing tools.

2.3.2. Linguistic Readiness

Linguistic readiness can be defined as the ability of learners to utilize the language resources adequately (Ruminar & Gayatri, 2024). Linguistic readiness in AI-assisted writing is imperative because learners need to actively analyze and improve AI-produced texts instead of passively receiving them (Cui, 2025).

Linguistic readiness in the present study is conceptualised as learners' perceived capability to perform academic writing tasks in English. Rather than representing objective linguistic competence, this dimension is operationalised through writing self-efficacy, which reflects learners' beliefs about their ability to generate ideas, organise content, and apply appropriate language resources in writing (Limpo & Alves, 2017).

2.3.3. Ethical and Responsible Awareness

According to Pramod (2025), ethical awareness can be understood as the cognitive awareness of the consequences of using AI tools in decisions related to society and justice. In academic writing, ethical awareness involves issues of academic integrity, plagiarism, authorship, and responsible usage of AI-generated content (Kobrossy et al., 2025)

Based on recent research concerning AI literacy, ethical awareness does not only involve understanding AI regulations but also responsible AI use in educational contexts. Ng et al. (2023) suggested learners should be equipped with the ability to critically reflect on the ethical use of AI tools, which includes attribution, originality and responsible writing.

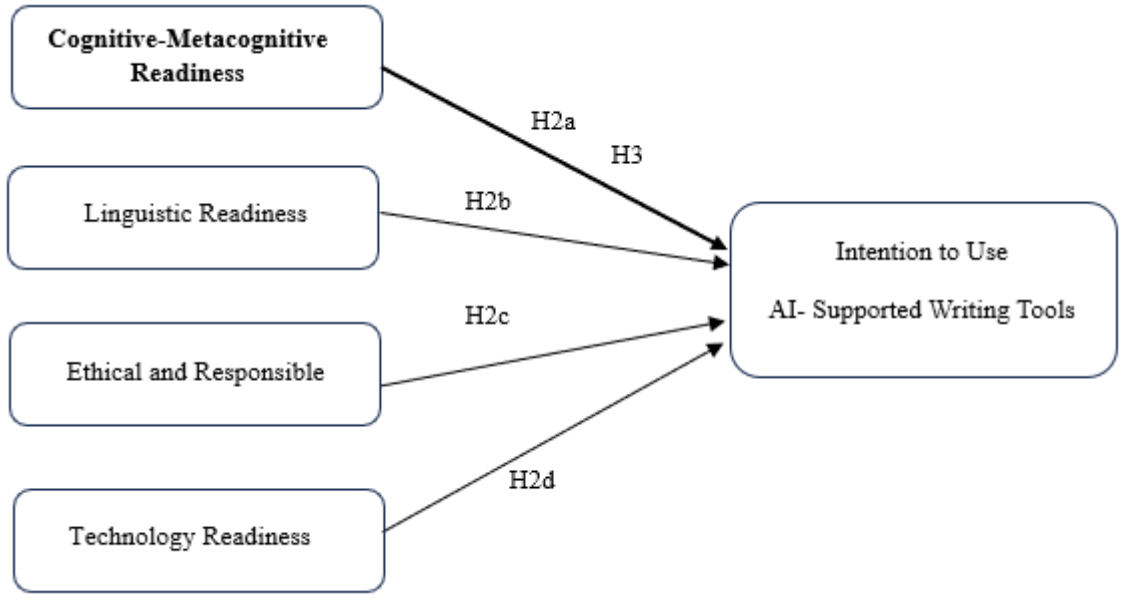
2.3.4. Technology Readiness

Technology readiness refers to an individual's disposition toward context-specific behaviors, namely, using new technologies for accomplishing goals (Parasuraman & Colby, 2015). The Tech Readiness Index (TRI) is based on this approach and is considered a gestalt of four personality scales: optimism and innovativeness are enablers, while discomfort and insecurity are inhibitors (Godoe & Johansen, 2012; Parasuraman, 2000).

Students who are more optimistic and innovative will actively apply various AI tools, but less comfortable and less secure students might be reluctant to use them successfully

(Marimon et al., 2025). Therefore, technology readiness is important in shaping learners' intention to use AI when writing (Rahman et al., 2025).

2.4. Intention to Use AI-Supported Writing Tools



The Technology Acceptance Model (TAM) posits that users' intention is a direct predictor of actual technology use (Davis, 1989). Within the realm of AI-based academic writing, intention to use represents students' engagement in planning how they integrate AI tools, rather than occasional use. Although TAM typically focuses on perceived usefulness and perceived ease of use, our study broadens this approach by considering intention to use as a result of learner readiness, which encompasses cognitive-metacognitive, linguistic, ethical and technological dimensions. Therefore, TAM provides a theoretical basis for the dependent variables, but not a holistic framework.

2.5. Conceptual Framework

Cognitive–metacognitive readiness was adapted from the self-regulated learning strategies proposed by Teng and Zhang (2016). Linguistic readiness drew on four components of the English Writing Self-Efficacy scales by Bi and Wang (2025). Ethical and responsible awareness was informed by Ng et al. (2023), while technology readiness was adapted from Cui (2025) and the Technology Readiness Index model (Parasuraman & Colby, 2015). The outcome variable, intention to use AI, was adapted from the Technology Acceptance Model (Davis, 1989). This integrated framework was developed to provide a holistic assessment of undergraduates' readiness within the context of English language studies, while situating intention to use as an outcome construct rather than a full acceptance framework (see Figure 1).

Figure 1

Conceptual Framework of Learner Readiness and Intention to Use AI-Supported Writing Tools

Note. H3 refers to the comparative predictive strength among the four readiness dimensions.

Based on this conceptual framework, this study proposes the following hypotheses:

H1. The four readiness dimensions are expected to be positively associated with students' intention to use AI-supported academic writing tools.

H2a. Cognitive–metacognitive readiness significantly predicts students' intention to use AI-supported academic writing tools.

H2b. Linguistic readiness significantly predicts students' intention to use AI-supported academic writing tools.

H2c. Ethical and responsible awareness significantly predicts students' intention to use AI-supported academic writing tools.

H2d. Technology readiness significantly predicts students' intention to use AI-supported academic writing tools.

H3. Among the four readiness dimensions, cognitive–metacognitive readiness is hypothesized to exert the strongest predictive effect on students' intention to use AI-supported academic writing tools.

3. Methodology

3.1. Research Design

This study employs a mixed-methods approach, incorporating both quantitative and qualitative methods. Quantitative data were collected through a structured questionnaire. Qualitative data were obtained from semi-structured interviews.

3.2. Participants

The participants comprised 93 English-major undergraduate students at Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT) (see Table 1).

Table 1

Participant Demographics (N = 93)

Variable	Category	n	%
Gender	Male	67	72
	Female	26	28
English proficiency	Intermediate	57	61.3
	Upper-intermediate	33	35.5
	Advanced	3	3.2
Frequently used AI tools	Generative AI tools (e.g., ChatGPT, Gemini, Claude)	88	94.6
	Grammar checking tools (e.g., Grammarly, ProWritingAid)	54	58.1
	Paraphrasing tools (e.g., QuillBot)	43	46.2
	Translation tools (e.g., DeepL/Google Translate)	29	31.2

Note. Percentages for AI tools exceed 100% because participants could select multiple responses.

All respondents were third-year students who had completed academic writing courses at the time of data collection.

Participants in the study were selected using a convenient sampling technique. Participation was voluntary, and all participants provided informed consent before data collection. Regarding prior experience with AI tools, most participants reported familiarity with Generative AI and grammar checkers.

3.3. Research Instruments

Two research instruments were employed: a questionnaire and semi-structured interviews.

The questionnaire included approximately 29 items measured on a five-point Likert scale ranging from strongly disagree to strongly agree. It was organized into seven sections: (1) introduction, (2) cognitive–metacognitive readiness, (3) linguistic readiness, (4) ethical & responsible AI awareness, (5) technology readiness, (6) intention to use AI in academic writing, (7) demographic information and AI usage background. To ensure linguistic accuracy and comprehensibility, the questionnaire was administered bilingually in English and Vietnamese using the back-translation technique. The overview of questionnaire dimensions, sources, and sample items is provided in Appendix A. In addition, five semi-structured interviews were also conducted to further explore students' experiences and perceptions of using AI in academic writing.

3.4. Data Collection Procedure

The online survey was deployed using Google Forms. Students also had easy access to the questionnaire since it was distributed through a QR code and could submit their responses immediately. After the data collection period, 93 entries were retrieved and uploaded to SPSS Statistics Version 26 software for quantitative analysis. Additionally, five semi-structured interviews were conducted through Zalo calls and recorded using the Audacity application. Each interview lasted approximately 20 minutes.

3.5. Data Analysis

Survey responses were obtained and summarized using descriptive statistics (mean and standard deviation). Moreover, Pearson correlation analysis was employed to test the relationship between variables, and the multiple regression analysis was conducted to determine predictors of students' intention to use AI-supported writing tools.

Qualitative data were analyzed using thematic analysis. Interview transcripts were coded and organized into themes in order to define the general trends and gain a more in-depth picture of the students' perceptions. Due to the anonymity of the participants, the interviewed students are referred to as S1 (Student 1), S2 (Student 2), and so forth.

3.6. Reliability and Validity

To ensure internal consistency, Cronbach's alpha coefficients were calculated for all sub-constructs in the questionnaire (see Appendix B). The results indicated acceptable reliability across the scales, with Cronbach's alpha values exceeding the threshold ($\alpha > .70$) for most dimensions. Following the Technology Readiness Index framework, technology readiness was examined as two distinct subdimensions: Technology Enablers and Technology Inhibitors. While Technology Enablers demonstrated satisfactory internal consistency ($\alpha > .70$), the reliability coefficient for Technology Inhibitors was slightly below the recommended threshold ($\alpha = .69$) but was still considered acceptable for an exploratory subscale (Hair et al., 2010; Taber, 2018).

Regarding validity, all measurement items were adapted from validated instruments in relevant studies. The questionnaire was administered bilingually in English and Vietnamese.

4. Results

4.1. Quantitative Results

4.1.1. Descriptive Statistics

The descriptive analysis was employed to analyse the degree of readiness of English-major undergraduates to write academic papers with the assistance of AI, based on four dimensions: (1) Cognitive - Metacognitive Readiness, (2) Linguistic Readiness, (3) Ethical and Responsible Awareness, and (4) Technology Readiness. Additionally, Technology Readiness has been categorised into two sub-constructs, Technology Enablers and Technology Inhibitors, to be explored deeply as discussed in the Methodology.

Table 2

Descriptive Statistics of Readiness Dimensions (N=93)

Readiness Dimensions	Mean (M)	Std. Deviation (SD)
Cognitive-Metacognitive	4.169	.570
Technology Enablers	4.149	.069
Ethical Awareness	4.141	.628
Technology Inhibitors	3.844	.893
Linguistic Readiness	3.688	.732
Intention to Use	4.096	.613

Note. Interpretation of Mean scores is based on the interval scale suggested by Pimentel (2010): 1.00–1.80 (Very Low); 1.81–2.60 (Low); 2.61–3.40 (Moderate); 3.41–4.20 (High); 4.21–5.00 (Very High).

The results in Table 2 revealed that the mean scores for all readiness dimensions ranged from 3.688 to 4.169. Cognitive-Metacognitive Readiness obtained the highest mean score (M = 4.169, SD = .570), although only marginally higher than Ethical Awareness (M = 4.141, SD = .628) and Technology Enablers (M = 4.149, SD = .069). Technology Inhibitors recorded a mean score of 3.844. The lowest mean score among the four dimensions was observed in Linguistic Readiness (M = 3.688, SD = .732). Regarding the dependent variable, the mean score for Intention to Use AI tools in academic writing was 4.096.

4.1.2. Correlation Analysis

The Pearson correlation results (see Table 3) indicated that all readiness dimensions, except Technology Inhibitors, had significant positive relationships with English major students' intention to use AI tools.

The strongest correlation was found between Technology Enablers and Intention (r = .635, p < .001), followed by Cognitive–metacognitive Readiness (r = .525, p < .001), Linguistic Readiness (r = .450, p < .001), and Ethical Awareness (r = .448, p < .001). Notably, Technology Inhibitors did not show a statistically significant correlation with intention (r = .167, p = .111).

Table 3

Pearson Correlation Matrix between Readiness Dimensions and Intention to Use AI (N=93)

Variables	1	2	3	4	5	6
1. Cognitive-Metacognitive	1					
2. Linguistic Readiness	.352**	1				
3. Ethical Awareness	.419**	.374**	1			
4. Technology Enablers	.552**	.483**	.512**	1		
5. Technology Inhibitors	.227*	.292**	.297**	.298**	1	
6. Intention to Use	.525**	.450**	.448**	.635**	.167	1
Sig. (2-tailed)	.000	.000	.000	.000	.111	

Note. p = Pearson's correlation coefficient; **(2-tailed): p-values < .01, *(2-tailed): p-values < .05

4.1.3. Multiple Regression Analysis

A multiple regression was conducted to identify the strongest predictors of intention. The model was statistically significant, $F(5, 87) = 16.064$, $p < .001$, explaining 48% of the variance in students' intention ($R^2 = .480$).

As shown in Table 4, Technology Enablers ($\beta = .404$, $p < .001$) and Cognitive-Metacognitive Readiness ($\beta = .216$, $p = .025$) were the only two significant predictors. Other factors, including Linguistic Readiness, Ethical Awareness, and Technology Inhibitors, did not substantially contribute to the model ($p > .05$). All VIF values were under 2.0, indicating that there are no issues related to multicollinearity.

Table 4

Multiple Regression Analysis Predicting Intention to Use AI (N=93)

Predictors	β	t	p	VIF
Cognitive-Metacognitive	.216	2.28	.025	1.505
Linguistic Readiness	.16	1.762	.082	1.383
Ethical Awareness	.115	1.23	.222	1.469
Technology: Enablers	.404	3.841	.000	1.851
Technology: Inhibitors	-.084	-1.007	.317	1.161

Note. Model Statistics: $R = .693$; $R^2 = .480$; Adjusted $R^2 = .450$; $F = 16.052$; $p < .001$.

4.2. Qualitative results

4.2.1. Cognitive–Metacognitive Readiness in AI-Supported Writing

All participants demonstrated clear awareness of the AI's limitations and mentioned critical thinking as an indispensable part of their writing process. However, clear differences emerged across proficiency levels. Upper-intermediate students (S1 and S5) exhibited strong metacognitive readiness through initiating questioning of the output reliability and establishing personal benchmarks.

"I use AI to assist me with brainstorming ideas. Right from the start, … I need to refine that topic to see if it's practically suitable, as well as get ideas on what exactly I should cover within that topic." (S1)

"Typically, I'm confident with a 70-30 ratio, where 70% comes from personal effort, and the remaining 30% comes from AI." (S5)

Conversely, intermediate students (S2 and S3) were more inclined to interact with AI tools through direct experience instead of anticipatory planning. Both S2 and S3 described the cases when AI provided them with inaccurate information and responded by cross-referencing with Google or other AI platforms.

4.2.2. Linguistic Readiness for AI Usage

The results of the interview illustrated the greatest distinction between the two proficiency groups. The upper-intermediate students emphasised that they primarily utilized AI to polish their expression and enhance academic writing skills, whereas the intermediate-proficiency students considered AI as one of the means to compensate for their language shortcomings.

"I could say I have to use AI to ask it things like, "How can I write this more formally?", and it guides me in several ways … AI is just there to support and give suggestions." (S1)

Specifically, S2 conveyed feelings of insecurity when comparing their own work to AI-generated texts and uncertainty about their ability to achieve the required score without that assistance.

"Sometimes, I feel like I'm becoming too dependent on this AI. And without it, I don't know how long it would take me to achieve my target score." (S2)

4.2.3. Ethical and Responsible Awareness in AI Use

All participants set boundaries on their AI usage, but their self-regulation mechanisms differed considerably. S1 made a clear distinction between "the application of AI tools to support" and "copy-paste". Additionally, S1 added "human perspectives" to prevent a mechanical writing style. S2 established a technical indicator of AI under 30 per cent. S3 used metaphors, the pillars and the roof, to illustrate a real sense of the border between support and replacement.

"The principle I always apply is that AI provides the foundation for my work. I just need to step up and build the pillars and roof myself to complete my part." (S3)

S5 applied the principle of using AI for one section, then independently wrote the following sections, demonstrating a remarkable finding regarding the structured self-regulation mechanism and practical applications of AI in academic writing.

4.2.4. Technology Readiness

All participants were in a positive state and ready to experiment with new tools. The approach to new tools was consistent, including trying with simple questions first, comparing with the old tools, and then applying it to the actual task (S2, S3, and S4). S1 focused on paid work and "training" AI according to individual needs.

"I have to train and evaluate AI's authenticity through data, difficult problems or things I pose for it to solve." (S1)

While S2 was the only case showing genuine concern about how much time they needed to reach their expected score without the AI support, the other participants perceived the risk of dependence but were not overly anxious. By contrast, neither upper-intermediate English learner was worried about AI disappearing.

5. Discussion

5.1. Students' Readiness for AI-Supported Academic Writing

Notably, the highest mean score (M = 4.17) of Cognitive-Metacognitive Readiness indicates that participants have self-regulated learning abilities, which entail the process of planning, monitoring, and evaluating AI-generated content. This result is consistent with the study of Tezer (2025), which showed that AI systems promote metacognitive engagement, an essential process that allows learners to acquire knowledge actively and adjust their learning methods strategically.

Simultaneously, the relatively high scores for Technology Enablers and Ethical Awareness dimensions suggested that students' intention to use AI may be associated not only with access to technology but also with responsible engagement with AI tools. This finding represents a broader understanding of AI literacy among EFL undergraduates, beyond technical proficiency, entailing the scope of evaluation, metacognition, and ethical responsibility in AI-supported academic writing practices (Adamakis & Rachiotis, 2025).

However, the mean score of the Technology Inhibitors was relatively low, suggesting that a group of learners still experienced digital anxiety and insecurity. This finding aligns with a study by Almusharraf (2026), which shows that learner anxiety is a relevant factor in the context of AI-assisted writing, where perceived usefulness is coupled with increased anxiety when using AI chatbots for writing in English as a second language.

The difference in mean values between Cognitive-Metacognitive Readiness and Linguistic Readiness can be interpreted through the self-regulated learning theory (Zimmerman, 2002), which assumes that learners become more sensitive to their linguistic constraints as they become more strategically aware. Recent studies indicate that students with an advanced metacognitive capacity are more readily engaged in the process of critical evaluation, revision, and strategic adaptation; thus, they are also more likely to become aware of the gaps in their linguistic accuracy and sensitivity (Sun & Wang, 2020; Teng, 2025).

The variations in AI readiness dimensions were further illuminated by qualitative data from participants with different levels of English proficiency. Even though all interviewees were conscious of the constraints of AI tools and the significance of critical thinking, upper-intermediate-English-level students displayed a greater level of self-management through the process of developing outlines, testing reliability and setting personal benchmarks. The intermediate-English-level students, in turn, were more passive in their attitude towards AI, as they mostly verified AI-generated texts only when they suddenly detected a potential error.

5.2. Relationships among Readiness Dimensions and Intention to Use AI

The results of the Pearson correlation analysis largely confirm Hypothesis H1, indicating that most aspects of readiness examined in this study are positively correlated with students' intention to use AI tools in academic writing. Specifically, the strongest bivariate association between Technology Enablers and Intention to Use implies that a positive and active approach toward technology identifies the willingness of students to adopt AI tools. This finding is aligned with the study of Dahri et al. (2024), who propose that the enabling conditions and the perceived self-efficacy within the AI-interacting environment are crucial determinants of AI adoption.

The fact that there was no statistically significant correlation between Technology Inhibitors and Intention to Use is further clarified by qualitative data. In other words, technological barriers do not seem sufficient to influence English major undergraduates'

intention to use AI. For upper intermediate-level students (S1, S5), AI tools play a more supportive than essential role; as a result, these students expressed little concern if AI becomes unavailable. Conversely, S2, an intermediate-level student, was particularly concerned that his grades might be affected without the support of AI tools.

Moreover, the relationship between Intention to Use and Ethical Awareness was further contextualized by the qualitative results. In particular, the interviewees demonstrated multiple attitudes towards the ethical responsibility of AI usage, such as balancing human-AI cooperation and complying with the principle of less than 30% AI content.

5.3. Predictive Power of Readiness Dimensions

The regression analysis results showed a differentiated pattern when considering the predictive power of readiness dimensions on EFL undergraduates' intention to adopt AI tools for academic writing. The regression coefficient of Cognitive-Metacognitive Readiness showed significant influence on Intention to Use, thus confirming Hypothesis H2a. Nevertheless, contrary to Hypothesis H3, which suggested that Cognitive-Metacognitive Readiness is the strongest predictor of Intention to Use, the regression results demonstrated that Technology Enablers had a more substantial predictive effect.

On the other hand, Technology Inhibitors did not have a statistically significant effect on Intention to Use, which implies that the sentiment of discomfort or insecurity can be alleviated by perceived benefits and increased familiarity with AI tools. Based on the current findings, optimism and willingness to experiment with AI appeared to be driving factors for technology use; this is in line with the Technology Readiness Index (Parasuraman, 2000), which suggests that a lack of anxiety does not necessarily mean that learners do not perceive barriers, such as concerns about reliability or over-reliance on AI. Additionally, these results correspond to a recent study that highlights the crucial role of positive beliefs about technology in influencing the intention to use AI (Sustangingrum & Haldaka, 2025).

In opposition to hypotheses H2b and H2c, Linguistic Readiness and Ethical Awareness were not significant predictors of Intention to Use in the multivariate model, even though both dimensions were significantly correlated with Intention to Use in the bivariate correlation analysis.

Taken together, these findings suggest that cognitive-metacognitive and ethical preparation play an essential role in guiding how AI is used, rather than directly determining students' intention to adopt AI. Nevertheless, EFL undergraduates' intention to apply AI in academic writing appears to be largely dependent on their attitudes towards technological support, previous positive experiences, and self-regulation in the use of AI tools.

6. Conclusion

In general, the descriptive results showed that the participants reported relatively high levels of readiness across the examined dimensions. Meanwhile, the findings of correlation analysis revealed that the majority of readiness dimensions were positively associated with the intention to use AI. However, the regression analysis results unveiled that the cognitive-metacognitive aspect did not exhibit the strongest predictive power. The technological enabling factor was found to have the highest predictive coefficient on the intention to use AI. On the other hand, linguistic readiness and ethical awareness, which are the critical factors of responsible use, did not significantly influence the adoption decisions.

Based on qualitative interview results, the study found that technological competence and positive attitude are the driving factors behind the intention of EFL students to utilize AI

in writing academic papers, yet cognitive and ethical preparation function as moderating and controlling factors in how AI is used rather than whether it is adopted.

7. Implications and Limitations

7.1. Theoretical Implications

The present study offers preliminary evidence that AI readiness in TESOL is a multidimensional construct, which needs to distinguish between cognitive-metacognitive readiness and technological support in predicting the intention of learners to use AI. Although metacognitive preparedness is the guarantee of the quality and integrity of AI-supported writing, positive beliefs and supporting technological aspects are the main factors that can influence the choice of learners to adopt AI, and future theoretical models should consider both the ability to exert influence and the support conditions offered by technology.

7.2. Pedagogical Implications

Given that students' intention to adopt AI is primarily driven by positive beliefs toward technological affordances, English writing instructors should design learning tasks that allow students to experience, compare, and evaluate multiple AI tools in academic writing contexts. To prevent overreliance, AI should be positioned as a controlled support mechanism at specific stages of the writing process, such as outlining, checking coherence, or editing. These tasks should be accompanied by structured reflection requirements, including short reflective writing (approximately 150–200 words) or an AI Use Declaration. Through these practices, learners are encouraged to regulate their AI usage and align technological affordances with ethical judgment. On an institutional level, universities should offer consistent directions on how AI can be utilized in academic writing and provide students with access to credible AI platforms.

7.3. Limitations and Future Research

Despite the significance of the contributions to the study, there are still limitations that need to be considered. Firstly, the sample size and the scope of the institution are limited, as only EFL students of one institution of higher learning were used. This may affect the generalizability to other learning contexts. Second, the cross-sectional design fails to provide the opportunity to monitor the transformation of the perceptions, attitudes, and behavior of learners towards the use of AI over time.

Consequently, future studies should extend to longitudinal studies to examine how AI readiness and intentions to use AI evolve during a course or training program. Moreover, empirical or quasi-experimental research may be performed to evaluate the effects of various models of AI integration in the teaching of academic writing.

Acknowledgments

The authors would like to express sincere gratitude to third-year students majoring in Business English, who voluntarily took part in this study. Special thanks are extended to Mr. Tran Thanh Tu, the lecturer of the Introduction to Business subject at HUFLIT, for allowing the survey to be conducted in his classes and for his constructive feedback.

Bionote

Tran Phuong Anh is an EFL teacher and researcher. She holds a Master's degree in English Linguistics from Ho Chi Minh City University of Foreign Languages and Information Technology. She is interested in academic essay writing and AI-assisted learning. She is dedicated to developing learner autonomy in English classrooms. She aspires to pursue a PhD in TESOL and Applied Linguistics, with a concentration in academic literacy and technology-enhanced language learning.

Ngo Thi Thu Hien is a master's graduate in English Language from Ho Chi Minh City University of Foreign Languages and Information Technology. She is now teaching online from home, including the Cambridge English program. She helps students build language competence and prepare for exams. She has also delivered a conference paper, advancing

research in English language teaching methods. Her research includes language teaching, motivation, and classroom techniques.

Appendix A

This appendix presents an overview of the questionnaire dimensions used in the study.

Table A1

Questionnaire Dimensions, Sources, and Sample Items

Dimension	**Theoretical Source(s)**	**No. of Items**	**Sample Item**
Cognitive–Metacognitive Readiness	Zimmerman (2002); Teng and Zhang (2016)	7	*Before writing, I use AI to search for related ideas and information to help me plan my composition.*
Linguistic Readiness	Bi and Wang (2025)	7	*I can organize AI-generated sentences into a logical and cohesive academic paragraph.*
Ethical Awareness	Ng et al. (2023);	5	*I evaluate whether the AI-generated information is derived from reliable and credible sources.*
Technology Enablers	Parasuraman and Colby (2015)	4	*I actively keep up with the latest AI developments to enhance my English learning and writing.*
Technology Inhibitors	Parasuraman and Colby (2015)	2	*I sometimes feel that AI tools are not helpful because they cannot explain writing concepts in a way I can understand.*
Intention to Use AI	Davis (1989)	4	*I intend to use AI tools to support my English academic writing in the next semester.*

Note. Table A1 summarizes the adapted theoretical source for each dimension, the number of items, and a typical sample survey question for each dimension. The full questionnaire is available upon request.

Appendix B

This appendix reports the reliability of the dimensions.

Table B1

The Reliability of Questionnaire Constructs

Construct	**No. of Items**	**Cronbach's Alpha (α)**
Cognitive–Metacognitive Readiness	7	.811
Linguistic Readiness	7	.853
Ethical Awareness	5	.783
Technology Enablers	4	.742
Technology Inhibitors	2	.690
Intention to Use	4	.757

Note. Cronbach's alpha values above .70 indicate acceptable internal consistency. The slightly lower alpha value for Technology Inhibitors is considered acceptable for an exploratory subscale with a limited number of items.

#41 Students' Perceptions of Google Meet in ESL-Oriented Online Cambridge Exam Preparation at Private Language Centers in Ho Chi Minh City

Ngô Thị Thu Hiền[1]

Abstract

As digital technology rapidly advances, online learning of English has become a new trend in numerous teaching environments. The purpose of this study is to examine how learners view ESL-focused online English learning using Google Meet in private classes of Cambridge exam preparation in Ho Chi Minh City. The study employed a mixed-method approach involving 35 KET and PET level students, utilizing semi-structured interviews and a Likert scale questionnaire analyzed through SPSS. Results indicated a positive perception of the online learning environment, with students appreciating communication with instructors and peers, and effectively using English. Google Meet features like screen sharing and chat were noted as beneficial for understanding and engagement. Limitations included a small sample size, suggesting future research should involve larger and more diverse groups to further explore digital technologies in online ESL learning.

Keywords: ICT, online ESL learning, Google Meet, digital tools

1. Introduction

In Vietnam, English as a foreign language (EFL) has always been taught with the classroom practices focusing more on grammar knowledge and test results than the application of meaningful use of language (Ha et al., 2021). Nevertheless, the growing academic, professional and international requirements towards the English language have contributed to the rising voices in favor of a change into an English as a Second Language (ESL) orientation, which is more communication-oriented, inter-personal and life-based in language use (Hsu, 2015). This shift has emerged as one of the main topics of recent debate about the English language education in Vietnam.

Meanwhile, online learning is now an element of the English language teaching, especially after the Covid-19 pandemic (Rintaningrum, 2023). Synchronous learning has also opened up new possibilities in interaction, sharing and exposure to the English language outside the classroom setting due to digital platforms (Procel et al., 2024). Google Meet is one of these platforms, as its availability, convenience, and integration with other computer technologies that facilitate online learning have become very popular (Al-Maroof, 2020).

The effectiveness of online applications in enhancing language skills and learning outcomes of students has been investigated in many studies such as studies by Al-Jarf (2026) and Popovici and Mironov (2015). Nevertheless, minimal studies have been conducted on the perceptions of ESL-based online teaching of English among learners in Vietnam in private classes of exam preparation in Cambridge English. The majority of past research is inclined to consider the general online learning settings or university setting instead of domestic language classes that prepare students to pass international English exams.

[1] *A graduate of the postgraduate program at Ho Chi Minh City University of Foreign Languages and Information Technology; Email: friendship200561@gmail.com*

Moreover, there are numerous tools offered by digital platforms like Google Meet that can support the interaction, communication, and engagement of online synchronous lessons (Eraković & Topalov, 2021). These tools could be successful in establishing an ESL-friendly learning atmosphere in which students are motivated to learn English actively during classroom practices. Nevertheless, the success of these tools is highly reliant on the perceptions and experiences of students of online learning.

The following research questions are addressed in the study:

RQ1: How do students perceive ESL-oriented online English learning through Google Meet in private classes of Cambridge exam preparation in Ho Chi Minh City?

RQ2: What is the perception of learners regarding digital tools utilization on Google Meet as an assistant to the processes of interaction, engagement, and communication in English concerning online ESL-oriented courses?

2. Literature Review

2.1 Information and Communication Technology (ICT) and development of e-learning

According to AlTameemy and Alrefaee (2021), ICT is becoming an increasingly important component of our daily lives, as it is a natural consequence of the significant advancements in modern technology. Adaptive e-learning is viewed as stimulation to support learning and improve student engagement, so designing appropriate adaptive e-learning environments contributes to personalizing instruction to reinforce learning outcomes (El-Sabagh, 2021). According to El-Seoud et al. (2014), E-learning has become increasingly important as a result of advancements in technology, significantly transforming higher education. The 21st century has witnessed rapid development in online learning, with enrolment increasing by 12-14 percent annually from 2004 to 2009. This growth is largely attributed to the flexibility e-learning offers, allowing students to access education from anywhere and at any time, with options for part-time or full-time study. Additionally, e-learning facilitates easier information sharing among students, enhancing educational experience.

2.2 EFL and ESL in English Language Education

According to Zhou et al., (2024), English language teaching has been long conceptualized in the context of the difference between English as Foreign Language (EFL) and English as Second Language (ESL). According to the research by Religioni et al (2024), ESL and EFL are differentiated by the context of learning and the level of language interaction. In an ESL setting, English exposure is more frequent and varied than in an EFL setting. More significantly, ESL offers greater chances of negotiating the meaning, as learners frequently request clarification and are presented with altered input by interlocutors. The frequency of adjustment and reformulation of the output is also promoted among ESL learners, which allows them to identify and address language issues. Sato and Storch (2020) explained that the difference between ESL and EFL settings is determined by learners' needs and purposes. On the cognitive and structural level, an ESL context facilitates language learning by offering more quality, quantity, and diversity of language input and multiple opportunities for use of the target language in both the classroom and out. Thus, ESL provides more productive conditions for acquiring a second language, compared to EFL.

2.3 Digital Tools and Synchronous Online English Learning

The quick growth of online education has revolutionized the education of English language, especially by adopting the synchronous digital platform (Moorhouse & Wong, 2021). Real-time communication between teachers and learners is possible with help of synchronous online learning environments providing an opportunity to use communicative language, to provide instant feedback and collaborate with teachers and other learners. A study by Radovan et al. (2020) integrates our experiences and comparative analysis of using different tools for online education during times where the usual teaching methods are not an option because of various restrictions related to travel bans, quarantines or virus pandemics. The tools being analyzed are Skype, Microsoft Teams, Adobe Connect and Zoom. Several aspects are analyzed including starting courses and creating groups of students, enrolling students to the class, delivering the lecture, communicating with the students during the class, getting feedback from the students in a virtual class, tracking student activity, creating live polls and questionnaires, sharing content, recoding audio and video content, submitting assignments and homework and accessing the archived content. Each explored aspect has a direct influence on the whole teaching and learning experience as well as the effectiveness of supporting the educational processes.

Google Meet is one of those that have gained popularity as a widely used platform because of its accessibility, ease of use and compatibility with other Google based applications (Al-Maroof et al., 2021). These characteristics enable educators to create engaging online courses that facilitate ESL-oriented practices even during exam preparation. Besides, the Google Meet platform is widely utilized for video conferencing in online learning, facilitating audiovisual communication between teachers and students in both small and large groups (Nehe, 2021). It offers various features that enhance online learning by allowing teachers to present materials and encourage interactive discussions (Purwoko et al., 2022). According to Yumnam (2021), Google Meet is accessible video conferencing platform suitable for both business meetings and online classes. These services allow users to log in via various devices. They facilitate live interaction between teachers and students, enabling the sharing of presentations and multimedia resources. In ESL classes, teachers can cover essential language skills using PowerPoint and interactive methods (Zahara & Jupri, 2022). While students can practice concepts through direct engagement with instructors, they are given the opportunity to practice the skills being learnt in real time and then are provided with scaffolding from their teacher that is empathetic and immediate, they move from being passive recipients to active problem solvers (Zhang, 2023).

2.4 Related Studies

Solihah (2023) discovered that Google Meet was an effective tool that facilitated online learning in a TOEFL preparation course by making the interaction between students and the lecturer real-time, boosting comprehension and motivation. The study by Pham and Nguyen (2023) shows that university students in Vietnam positively perceived the use of Google tools—Google Classroom, Google Forms, Google Meet, and Google Sites—for learning English. These tools enhanced their educational experience and improved their progress in English, highlighting the effectiveness of Google products in language instruction and suggesting avenues for further research in online English education technologies. The research by Yumnam (2021) established that e-learning is an efficient means of teaching ESL since it helps improve language of students, boosts their interaction and offers them flexibility in learning, but proper technological support and planning are needed to implement it effectually.

3. Methodology

3.1 Research Design

In order to obtain data to conduct this mixed-method study, a questionnaire and semi-structured interviews were used. The questionnaire itself was a set of Likert-scale items created with the help of Cognito Forms with 1-5 inherent to the statement of Strongly Disagree and Strongly Agree respectively. The questionnaire employed in the current study was adapted modified from Delviyanti et al. (2022) for the context of online Cambridge exam preparation classes. The method of questionnaire was chosen because it made it possible to gather systematized information about the opinions of the learners concerning the use of language, interaction, engagement, and the contribution of digital tools into the online learning settings. The research aimed at the description of the perceptions of the learners, not quantifying the learning results or causal relationships. Furthermore, semi-structured interviews were carried out with some volunteer students to gain deeper insights into their perception of online learning of the English language through Google Meet. The interviews were held with the help of Google Meet video calls and took about 25 minutes.

3.2 Participants

The respondents used in this research were 35 students who are taking privately online classes in Cambridge English examination preparation in Ho Chi Minh City in Vietnam. The learners were KET and PET level. Everyone possesses a minimum of 1 year's experience in utilizing Google Meet for learning purposes. The two levels of proficiency were chosen because the learners were deemed as mature and linguistically competent enough to appreciate the questionnaire items and give credible self-reported answers.

KET and PET learners were generally capable of sufficient reading comprehension and had previous exposure to online learning in English, which allowed them to reflect on the learning experience and attitudes towards ESL-oriented online learning. Younger learners in lower levels of Cambridge were, on the contrary, excluded because of age factors such as cognitive and linguistic constraints that could have compromised the validity of the questionnaire answers.

3.3 Data Collection Procedures

The questionnaire was conducted via Cognito Forms after the students had received ESL-focused English lesson via Google Meet. The participants had one week to answer the questionnaire, guaranteeing time for thoughtful consideration. The questionnaire was administered as an online survey, and students filled it out on their own in preparation time. All responses were received within the allotted seven-day time frame.

Following this step, five students were invited to take part in an online semi- structured interview through Google Meet. The interview took almost 25 minutes. The interviews were conducted and then transcribed and coded thematic interview protocols.

3.4 Data analysis

Data obtained from the questionnaires was analyzed in SPSS Version 26 (Statistical Package for the Social Sciences). All responses were screened for completeness and correct answers before analysis. Descriptive statistical analyses were to summarize the learners' perceptions, Mean, standard deviation and percentage. The interview data included content analysis, a process that involves collecting and interpreting data based on related concepts and topics. Quantitative data can be dealt with statistical analysis to help explain the patterns and frequency of the issue, while qualitative data from interviews provide profound insights.

3.5 Reliability

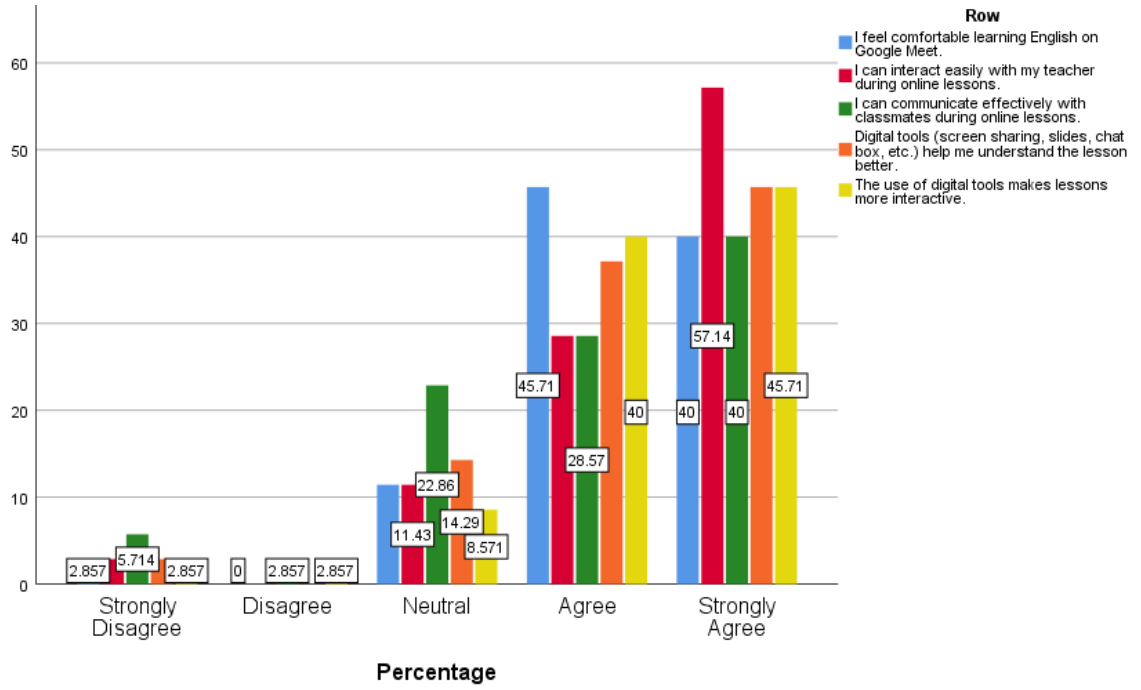
The Statistical Package for the Social Sciences (SPSS) version 26 was used to determine the Cronbach alpha in order to make sure that the questionnaire was reliable. The scores revealed that the constructs had acceptable reliability with alpha ranging between 0.879 and 0.912 (see Table 1). This indicates that the questionnaire questions were internally reliable and could be analyzed further.

Table 1

Reliability of the questionnaire and constructs

Constructs	N of items	Cronbach's Alpha value
Google Meet and Digital Tools	5	0.879
ESL-Oriented Language Use	5	0.891
Teaching Practices and Communication	5	0.897
Engagement and Overall Perception	5	0.907
Total	20	0.963

4. Findings

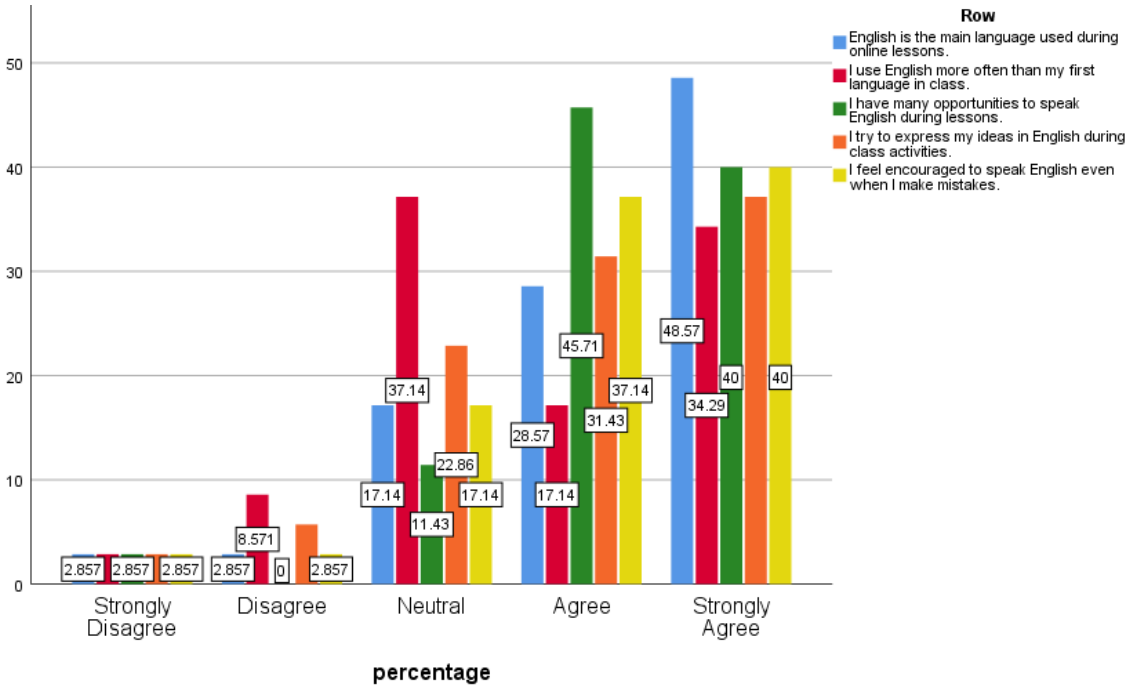


4.1 Findings from questionnaire

4.1.1 Google Meet and Digital Tools

The results shown in Figure 1 indicate that the perceptions of the students about learning English through Google Meet were very positive. There was a high percentage of students who said that they were at ease learning on the platform with 45.71% responding in the affirmative, and 40 percent strongly affirming this statement (M=4.20, S.D.=0.868). Regarding contact with the teacher, 28.57 and 57.14 percent agreed and strongly agreed that they could easily interact with the teacher during online lessons (M=4.37, S.D.=0.910). Likewise, when it comes to communication with classmates, 28.57% agreed and 40% communicate effectively in online classes (M=3.94, S.D.=1.136). Utilization of digital tools also received a positive response with 37.14 percent of the respondents agreeing to the tool and 45.71 percent strongly agreeing that the tool assisted them to understand the lesson better (M=4.23, S.D.=0.910). In addition, 40% and 45.71% responded that the lessons were more interactive with the help of digital tools and strongly agree, respectively (M=4.23, S.D.=0.942). Altogether, the agreement rates are quite high, which proves that Google Meet and its online resources are effective to support the learning of English online among students.

Figure 1

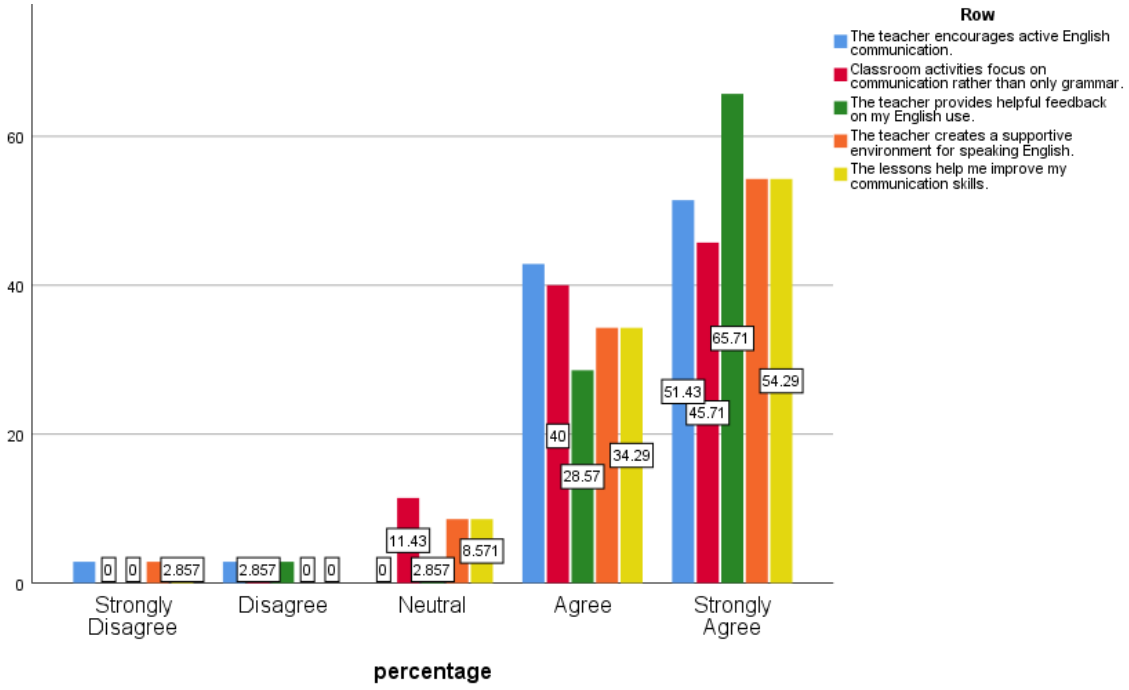


Google Meet and Digital Tools

4.1.2 ESL-Oriented Language Use

Figure 2.

ESL-Oriented Language Use



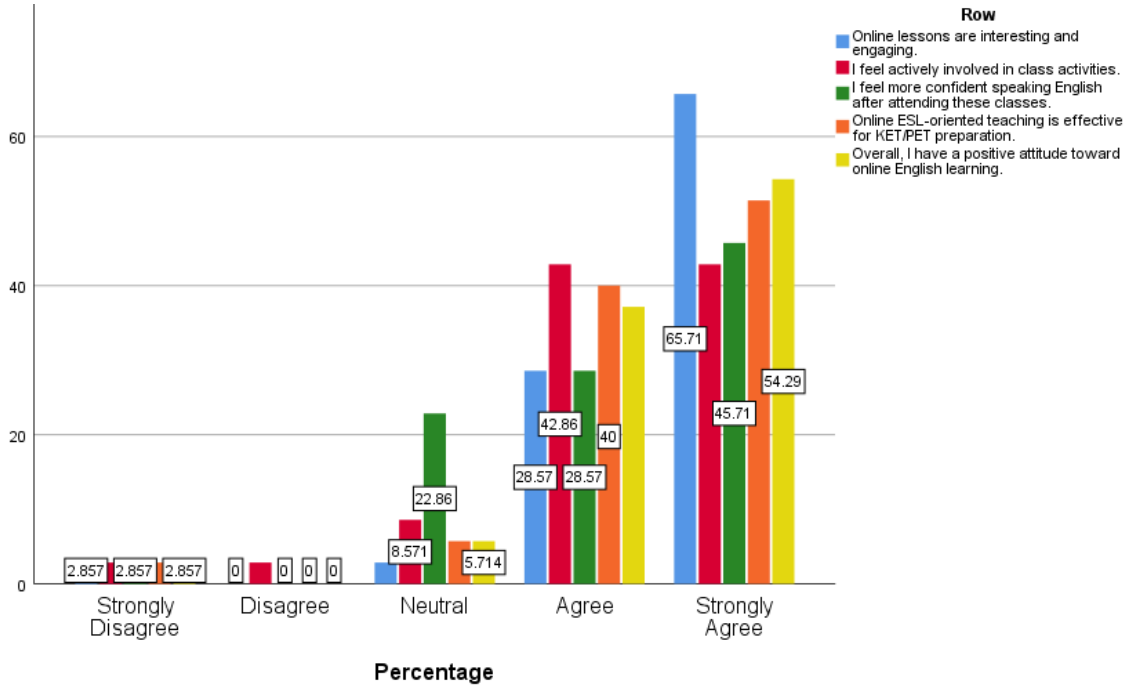
There are also positive results when it comes to the use of English by students during online lessons. Many students also stated that English was the primary language spoken in the classroom with 28.57 percent of students agreeing with this and 48.57 percent strongly agreeing (M=4.17, S.D.=1.014). In the same way, 17.14% answered in the affirmative and 34.29%

answered strongly in the affirmative that they more frequently used English than their first language in classes (M=3.71, S.D.=1.126). Concerning speaking opportunities, 45.71% had agreed and 40% strongly agreed that they had numerous opportunities to speak English online classes (M=4.2, S.D.=0.868). Besides, 31.43% of them agreed and 37.14% strongly agreed that they attempted to demonstrate their ideas in English when doing class tasks (M=3.94, S.D.=1.056). Lastly 37.14 percent said yes, and 40 percent said strongly that they were encouraged to talk English even when they made a mistake (M=4.09, S.D.=0.981). All in all, the percentages of agreement are high, which implies that the online learning environment facilitated active use of English among students in classes.

4.1.3 Teaching Practices and Communication

Figure 3.

Teaching Practices and Communication



The findings also reveal favorable attitudes of instructional activities in the online English lesson. Most of the students indicated that the teacher supported active communication in English as 42.86% and 51.43% students were of the view that it was true and strongly true respectively (M=4.37, S.D.=0.877). On the same note, 40 percent of them said that they agree, and 45.71 percent strongly agreed that classroom practices centered on communication as opposed to grammar (M=4.29, S.D.=0.789). As far as feedback is concerned, 28.57% of the respondents had to agree and 65.71% strongly agreed that the teacher gave them useful feedback on how they used English (M=4.57, S.D.=0.698). Moreover, 34.29% said that the teacher provided a favorable environment to speak English and 54.29% said strongly (M=4.37, S.D.=0.877). Lastly, 34.29% concurred with the statement that the lessons assisted them in improving their communication skills and 54.29% strongly concurred with the statement (M=4.37, S.D.=0.877). In general, these results indicate that the instructional method was effective in helping students in the online classroom to develop in the communicative language.

4.1.4 Engagement and Overall Perception

Figure 4.

Engagement and Overall Perception

The findings also indicate good attitudes to online learning of English among the students as well as high engagement and effectiveness. Most students said that they found online lessons interesting and engaging with 28.57% agreeing and 65.71% strongly agreeing (M=4.54, S.D.=0.817). Likewise, 42.86% of them agreed and 45.71% strongly agreed that they were actively engaged in the activities in classes (M=4.20, S.D.=0.933). Regarding the aspect of speaking confidence, 28.57 percent answered that they agreed, and 45.71 percent strongly agreed that they felt much more confident speaking English after taking these classes (M=4.14, S.D.=0.974). Besides, 40 percent and 51.43 percent consented and strongly consented to the ESL-oriented teaching approach as effective in the preparation of KET/PET (M=4.37, S.D.=0.843). Lastly, 37.14% chose yes and 54.29% chose strongly yes that they had an overall positive attitude toward online learning of English (M=4.40, S.D.=0.847). Generally, the large percentages of agreement indicate that the online classes were effective in fostering engagement of the students, their confidence, and positive attitudes towards learning.

4.2 Findings from interviews

The thematic analysis was the method used to analyze qualitative data gained during semi-structured interviews. The responses of the students elicited two key themes: positive attitudes towards the online learning of English and supportive functions of digital tools in the online interaction and communication.

4.2.1 Positive attitudes towards the online learning of English

Majority of students indicated that they felt good about learning English via Google Meet. They added that online education was convenient as they could learn at home and at the same time communicate with their instructors and peers. Other students also said that they were comfortable attending online classes and working on speaking exercises. The opinions of some students are as follows:

“I think learning English on Google Meet is very convenient. I can study at home and still talk with my teacher and classmates.” (S1)

“I like learning English on Google Meet because the teacher explains clearly and I can see the slides easily.” (S2)

“For me, learning online is interesting. We can practice speaking and answering questions in class. (S3)

“I think Google Meet helps me feel comfortable when learning English. I am not afraid to speak in class.” (S4)

“I enjoy my online English class because the teacher gives many activities and we can practice English together.” (S5)

4.2.2 Supportive functions of digital tools in the online interaction and communication

Digital tools and the interaction and understanding process. Another aspect is that students emphasized the significance of digital tools applied in online lessons. The use of screen sharing, slides, and the chat box feature enabled the students to have a better comprehension of the lesson and engage in classroom activities. Some of the students said that these tools made the lessons more interesting and made them feel more comfortable speaking English. Indicatively, a student said, “The teacher shares slides on the screen, so I can understand the lesson better” (S1). “When the teacher shows pictures and exercises on the screen, it helps me practice English more easily” (S3). “The chat box helps me answer questions and ask the teacher when I do not understand.” (S2). Likewise, another student observed that Digital tools make it more entertaining, and I feel more engaged in the classroom “Digital tools make the lesson more interesting, and I feel more active in class” (S4). Lastly, there was also more confidence in communication “I think the tools help me speak and answer questions in English more confidently.” (S5).

In general, the interview findings indicated that students gave positive ratings on the perception of online English learning via Google Meet and thought that the digital tools were significant in facilitating interaction, engagement, and communication in online ESL-oriented courses.

5. Discussion

This study was aimed at exploring how ESL-oriented online English teaching by using Google Meet is perceived by learners in private classes on Cambridge exam preparation in Ho Chi Minh City. Moreover, the research examined the perceptions of students towards the use of digital tools on Google Meet to facilitate interaction, engagement, and communication during online classes.

RQ1: How do students perceive ESL-oriented online English learning through Google meet in private classes of Cambridge exam preparation in Ho Chi Minh City?

Concerning the general perceptions of online ESL-based learning among the students, the results showed that most of the students had positive perceptions about learning English using Google meet, with 45.71% feeling comfortable using the platform. They actively engaged with teachers and peers and positively viewed the digital tools' role in enhancing comprehension. Approximately 48.57% reported that English was used frequently in class, and many felt encouraged to communicate despite errors. Students expressed favorable attitudes towards instructional activities, appreciating teacher support and feedback effectiveness. Engagement levels were high, with 65.71% finding online lessons engaging and 45.71%

feeling more confident in their English-speaking abilities after classes. These findings were further supported by the interview data, in which students reported that learning through Google Meet was convenient and allowed them to communicate effectively. These findings are in line with the earlier studies by Yumnam (2021) and Purwoko et al. (2022) that have indicated that online learning environment can be used successfully as a means of facilitating communication and interaction in language learning settings.

RQ2: What is the perception of learners regarding digital tools utilization on Google Meet as an assistant to the processes of interaction, engagement, and communication in English concerning online ESL-oriented courses?

The results indicated that digital tools are very crucial in improving the learning experience of students. According to the questionnaire results, most students (around 82 percent) found the use of such tools as screen sharing, slides, and chat functions to be helpful in enhancing their understanding and engagement. This was supported by the answers of the interviews where the students said that these tools made lessons engaging, allowed them to follow the material easier and became more confident with their use of English. The results are consistent with the existing studies such as the study by Solihah (2023), suggesting that online learning can be supported using digital tools that can help to improve the engagement of learners, their interaction, and communication.

In general, the findings of the current paper indicate that a successful online learning experience can be achieved through the combination of communicative teaching methods and digital tools when using such a platform as Google Meet. This kind of environment may motivate students to use English actively, communicate with their teacher and colleagues, and attend online ESL-oriented classes with greater confidence.

6. Conclusion and Implications

The research examined the perceptions of students regarding ESL-based online teaching of English via Google Meet during the private classes in preparation of Cambridge exams in Ho Chi Minh City. The findings indicated that most of the students were positive about the online learning environment. Students said that they could communicate with their teacher and classmates, speak English in the classroom and feel encouraged to express their ideas. Moreover, online technologies like screensharing, slides, and chat applications assisted students in learning lessons more effectively and provided more interaction in a classroom. All in all, the results indicate that the application of Google Meet along with communicative teaching and digital tools could be effective as an effort to support the process of interaction, engagement, and communication in online ESL classes.

First, the sample size was not very large, consisting of 35 students of the private classes to prepare to Cambridge exams in Ho Chi Minh City, which might affect the generalization of the results. Second, the study involved questionnaires and interviews, but there were only a few participants in interviews, which means that the qualitative data might not be comprehensive and reflect the results of all students. Lastly, the research could not include any learners other than KET and PET; hence, the results are not necessarily applicable to learners with different proficiency levels.

On pedagogical level, educators are advised to develop communicative lessons and competently use digital technology to improve interaction and engage students in online learning. The following studies might include larger samples, learners of varying proficiency, and other types of data collection aimed at further investigation of the influence of online technologies on language learning of students.

Questionnaire (English Version)

Learners' Perceptions of ESL-Oriented Online English Teaching via Google Meet: A Questionnaire-Based Study in Private Cambridge Exam Preparation Classes in Ho Chi Minh City

Hi everyone!

I am researching the Learners' Perceptions of ESL-Oriented Online English Teaching via Google Meet in Private Cambridge Exam Preparation Classes in Ho Chi Minh City. The findings can offer some information about the potential of using digital tools on Google Meet to help students feel confident and communicate within online ESL learning spaces, so I appreciate your collaboration. Thank you so much!

Part 1: Demographics

Please answer the following question for your personal information

1. Gender:

Male

Female

N/A

2. Age:

6-8

9-10

Over 10

3. How many years have you been learning English?

Less than 3 years

3-4 years

4-5 years

Over 5 years

4. How long have you been learning English online??

1 year

2-3 years

More than 3 years

Part 2: Learners' Perceptions of ESL-Oriented Online English Teaching via Google Meet

Please choose the appropriate number

1= Strong Disagree

2= Disagree

3= Neutral

4= Agree

5= Strong agree

	1	2	3	4	5
Google Meet & Digital Tools					
I feel comfortable learning English on Google Meet.					
I can interact easily with my teacher during online lessons.					
I can communicate effectively with classmates during online lessons.					
Digital tools (screen sharing, slides, chat box, etc.) help me understand the lesson better.					
The use of digital tools makes lessons more interactive.					
	1	2	3	4	5
ESL-Oriented Language Use					
English is the main language used during online lessons.					
I use English more often than my first language in class.					
I have many opportunities to speak English during lessons.					
I try to express my ideas in English during class activities.					
I feel encouraged to speak English even when I make mistakes.					
Teaching Practices and Communication	1	2	3	4	5
The teacher encourages active English communication.					
Classroom activities focus on communication rather than only grammar.					
The teacher provides helpful feedback on my English use.					
The teacher creates a supportive environment for speaking English.					
The lessons help me improve my communication skills.					

Engagement and Overall Perception	1	2	3	4	5
Online lessons are interesting and engaging.					
I feel actively involved in class activities.					
I feel more confident speaking English after attending these classes.					
Online ESL-oriented teaching is effective for KET/PET preparation.					
Overall, I have a positive attitude toward online English learning.					

Thank you for your cooperation!

APPENDIX B

QUESTIONNAIRE (Vietnamese version)

Đề tài: Nhận thức của người học về việc dạy tiếng Anh trực tuyến theo định hướng ESL qua Google Meet: Một nghiên cứu dựa trên bảng hỏi trong các lớp chuẩn bị kỳ thi Cambridge tư nhân tại Thành phố Hồ Chí Minh

Chào các bạn học viên!

Cô đang nghiên cứu về nhận thức của người học về giảng dạy Tiếng Anh trực tuyến theo định hướng ESL qua Google Meet trong các lớp chuẩn bị kỳ thi Cambridge tư nhân tại Thành phố Hồ Chí Minh. Kết quả của nghiên cứu có thể cung cấp một số thông tin về tiềm năng của việc sử dụng các công cụ kỹ thuật số trên Google Meet để giúp học sinh cảm thấy tự tin và giao tiếp trong các không gian học tập ESL trực tuyến, vì vậy cô rất trân trọng sự hợp tác của bạn. Cảm ơn các bạn rất nhiều!

Phần 1: Thông tin cá nhân

Vui lòng trả lời câu hỏi sau để cung cấp thông tin cá nhân của bạn.
1. Giới tính:
Nam
Nữ
Không xác định
2. Độ tuổi:
6-8
9-10
Trên 10
3. Bạn đã học tiếng Anh được bao nhiêu năm?
Ít hơn 3 năm
3-4 năm
4-5 năm
Hơn 5 năm
4. Bạn đã học tiếng Anh trực tuyến được bao lâu rồi?
1 năm
2-3 năm
Hơn 3 năm
Phần 2: Nhận thức của người học về việc dạy tiếng Anh trực tuyến theo định hướng ESL qua Google Meet
Vui lòng chọn số thích hợp
1= Rất không đồng ý
2= Không đồng ý
3= Trung lập
4= Đồng ý
5= Rất đồng ý

	1	2	3	4	5
Google Meet & Công Cụ Kỹ Thuật Số					
Tôi cảm thấy thoải mái khi học tiếng Anh trên Google Meet.					

Tôi có thể tương tác dễ dàng với giáo viên của mình trong các bài học trực tuyến.					
Tôi có thể giao tiếp hiệu quả với các bạn học trong các bài học trực tuyến.					
Các công cụ kỹ thuật số (chia sẻ màn hình, slide, hộp chat, v.v.) giúp tôi hiểu bài học tốt hơn.					
Công cụ số giúp giờ học thú vị hơn.					
Sử Dụng Ngôn Ngữ Hướng Đến ESL	1	2	3	4	5
Tiếng Anh là ngôn ngữ chính được sử dụng trong các bài học trực tuyến.					
Tôi sử dụng tiếng Anh thường xuyên hơn so với ngôn ngữ mẹ đẻ của mình trong lớp học.					
Tôi có nhiều cơ hội để nói tiếng Anh trong các tiết học.					
Tôi cố gắng diễn đạt ý tưởng của mình bằng tiếng Anh trong các hoạt động trên lớp.					
Tôi cảm thấy tự tin nói tiếng Anh dù có sai.					
Thực hành giảng dạy & Giao tiếp	1	2	3	4	5
Cô khuyến khích tôi nói tiếng Anh nhiều.					
Hoạt động trên lớp chủ yếu để giao tiếp, không chỉ học ngữ pháp.					
Cô sửa và góp ý giúp tôi nói tiếng Anh tốt hơn.					
Cô tạo không khí thoải mái để tôi nói tiếng Anh.					
Bài học giúp tôi giao tiếp tiếng Anh tốt hơn.					
Sự tham gia & Nhận thức tổng thể	1	2	3	4	5
Các bài học trực tuyến thú vị và hấp dẫn.					
Tôi cảm thấy mình tham gia tích cực vào các hoạt động trên lớp.					

Tôi cảm thấy tự tin hơn khi nói tiếng Anh sau khi tham gia các lớp học này.					
Giáo dục trực tuyến hướng đến ESL hiệu quả cho việc chuẩn bị thi KET/PET.					
Nhìn chung, tôi có thái độ tích cực đối với việc học tiếng Anh trực tuyến.					

Cảm ơn sự hợp tác của các bạn!

Interview Questions

1. How do you feel about learning English via Google Meet in your Cambridge exam preparation course?
2. What do you think of digital tools in Google Meet (screen sharing, slides, chat) that enable you to interact, participate, and communicate in English in an online lesson?

#42 Examining the Relationship between AI-Supported Self-Regulated Learning and Speaking Self-Efficacy among Vietnamese EFL University Students

Hoang The Hai Nguyen

Abstract

Artificial intelligence (AI) has increasingly become integrated into English as a foreign language (EFL) education, providing learners with new chances to plan, monitor, and regulate their language learning. However, the relationship between AI-supported self-regulated learning (AI-SRL) in speaking skills and learners' speaking self-efficacy remains underexplored, particularly in Vietnamese higher education. This study adopted a cross-sectional quantitative correlational design to examine the reported levels of AI-SRL and speaking self-efficacy and the relationship between the two constructs among 186 EFL students at a private university in Vietnam. A structured questionnaire was used for data collection and analyzed by descriptive statistics, reliability analysis, exploratory factor analysis and pearson's product–moment correlation. The results showed that both AI-SRL and speaking self-efficacy were reported at levels above the midpoint of the five-point scale. A statistically significant moderate positive correlation was also found between the two constructs ($r = .458$, $p < .001$), indicating that students who reported stronger regulation of their AI-supported speaking practice also tended to report stronger beliefs in their capability to perform English-speaking tasks. Because the study employed a cross-sectional correlational design, the findings do not establish a causal relationship between AI-SRL and speaking self-efficacy. Instead, they provide context-specific evidence of an association between learners' reported regulatory behaviour during AI-supported speaking practice and their perceived speaking capability.

Keywords: AI-supported self-regulated learning, speaking self-efficacy, EFL university students, artificial intelligence, Vietnamese higher education

1. Introduction

Artificial intelligence (AI) has increasingly become visible in English as a foreign language (EFL), providing learners with new chances for interaction, feedback, and language practice (Kohnke et al., 2023; Lai & Lee, 2024). Speaking is one of the most useful aspects. Recent studies of AI-supported speaking have reported positive outcomes related to speaking skills, willingness to communicate, confidence, and learner engagement (Du & Daniel, 2024; Fathi et al., 2024). Generative AI can literally support interactive exchanges and provide language-related feedback, while automated speech recognition (ASR) can give learners information based on their spoken production (Kohnke et al., 2023; Sun, 2023). For example, Sun (2023) found that ASR-supported practice was associated with improvements in pronunciation and broader speaking skills among EFL learners. Together, these findings suggest that AI can extend opportunities for learners to practise and review spoken English beyond regular classroom interaction.

AI-supported speaking practice may also shape how learners experience oral communication (Fathi et al., 2024; Wang et al., 2024; Zhang et al., 2024). Zhang et al. (2024) found that EFL learners practicing with an AI-speaking assistant showed lower foreign language anxiety and greater willingness to communicate after the intervention. Similar findings have been reported in research on conversational generative AI, although outcomes

may vary depending on the type of tool and interaction provided (Wang et al., 2024). These studies suggest that AI-supported environments can provide useful conditions for repeated speaking practice.

Chang and Sun's (2024) systematic review showed that AI has been used to support different stages of self-regulated language learning, while more recent work has examined how EFL learners plan, use strategies, monitor progress, and reflect in AI-supported environments (Hou & Zhou, 2025). These findings point to an important distinction between simply using an AI tool and regulating learning while using it. For example, one learner may use AI mainly to obtain an answer or correction, whereas another may set a goal, examine feedback, compare attempts, and decide what to practise next. The difference lies partly in how learners manage the learning process.

Self-regulated learning (SRL) provides a useful framework for examining this difference. Recent research describes SRL as a proactive and adaptive process in which learners plan and adjust their thoughts and actions in relation to learning goals (Pan et al., 2025). In AI-supported language learning, regulation may involve goal setting, strategic use of AI resources, monitoring, feedback evaluation, and reflection across different stages of learning (Chang & Sun, 2024; Hou & Zhou, 2025). These processes are cyclical rather than limited to a single learning event, as information gained from one attempt can influence how learners approach later practice (Chang & Sun, 2024).

Within the speaking context, these self-regulatory processes are directly translated into strategic learning decisions (Zimmerman, 2000, 2002). An autonomous learner may diagnose specific oral difficulties, select appropriate conversational AI tasks, monitor online speaking fluency, evaluate automated feedback, and refine speaking strategies for future practice behaviors that are increasingly prominent in AI-mediated EFL speaking environments (Du & Daniel, 2024; Panadero, 2017; Zimmerman, 2002). Although conversational AI provides rich opportunities for oral communication, the ultimate learning gains depend on how students interpret and utilize technological feedback, highlighting the need for active strategic control over digital resources (Hou & Zhou, 2025; Lai & Gu, 2011; Tseng et al., 2006). Therefore, this study defines AI-supported self-regulated learning (AI-SRL) as the extent to which learners plan, monitor, evaluate, and adjust their AI-supported English-speaking practice, adapting classic SRL frameworks to contemporary generative AI learning contexts (Chang & Sun, 2024; Pintrich, 2000; Su et al., 2023)."Speaking self-efficacy is another learner-related factor relevant to this process. In second-language research, self-efficacy refers to learners' beliefs about their capability to perform particular language tasks successfully (Li & Zhang, 2023; Phipps, 2024). It is therefore different from objectively measured language ability. Learners with similar levels of speaking performance may not necessarily evaluate their own speaking capability in the same way. Phipps (2024), for example, found that speaking self-efficacy among university EFL learners changed over time and was related to how learners evaluated speaking outcomes. Li and Zhang (2023) also reported dynamic relationships between speaking self-efficacy and the development of speaking accuracy and fluency in online-supported learning. These findings indicate that speaking self-efficacy can develop through learners' experiences of speaking practice and their interpretations of those experiences.

There is also a theoretical reason to consider speaking self-efficacy together with self-regulation. Derakhshan and Fathi (2024) examined self-efficacy, self-regulation, and L2 speaking performance within the same model and found that both learner factors were meaningfully connected with speaking performance. Although their study did not focus on AI-supported speaking, it suggests that self-regulation and self-efficacy can be examined together

within the broader process of L2 speaking development. Research on AI-supported SRL adds another dimension by showing that learners may plan, monitor, and reflect while using AI-supported resources for language learning (Chang & Sun, 2024; Hou & Zhou, 2025).

A possible connection between AI-SRL and speaking self-efficacy may emerge through repeated speaking practice. Monitoring and feedback evaluation can provide learners with information about what has improved and what remains difficult. Such information may become relevant when learners judge what they believe they are capable of doing in later speaking tasks. At the same time, learners' existing speaking self-efficacy may also be related to how they approach practice, respond to difficulty, and evaluate their learning experiences (Li & Zhang, 2023; Phipps, 2024). The relationship may therefore operate in more than one direction. For this reason, the present study does not assume that stronger AI-SRL leads to higher speaking self-efficacy or that higher speaking self-efficacy leads to stronger AI-SRL. Instead, it examines whether the two constructs are statistically associated.

Existing research has addressed different parts of this issue, but the specific relationship remains underexplored. Studies of conversational AI and AI-supported speaking have mainly focused on speaking outcomes, learner perceptions, anxiety, willingness to communicate, and the affordances of AI tools (Du & Daniel, 2024; Fathi et al., 2024; Lai & Lee, 2024; Zhang et al., 2024). Another line of research has begun to examine self-regulation in AI-supported language learning (Chang & Sun, 2024; Hou & Zhou, 2025; Pan et al., 2025). Speaking research has separately examined self-efficacy and its relationship with speaking development, performance, and self-regulation (Derakhshan & Fathi, 2024; Li & Zhang, 2023; Phipps, 2024). Although these studies provide important foundations for the present research, it remains less clear whether learners who report stronger self-regulation specifically during AI-supported speaking practice also report stronger speaking self-efficacy.

This question is particularly relevant in the Vietnamese EFL context. Duong and Suppasetseree (2024) investigated AI voice-chatbot practice among Vietnamese undergraduate students and reported significant improvement in English-speaking skills after an eight-week intervention. Their study demonstrates that AI-supported speaking has already become a relevant area of research in Vietnamese higher education. Ngo et al. (2025) also examined Vietnamese EFL undergraduates' AI use, self-efficacy, and self-directed learning and reported a positive relationship between self-efficacy in using AI and self-directed learning with AI.

However, the constructs examined in these studies differ from those used in the present research. Duong and Suppasetseree (2024) focused on speaking performance following AI-supported practice rather than learners' self-regulation during that practice. Cong-Lem et al. (2025) examined Vietnamese EFL learners’ self-efficacy in using generative AI tools, whereas the present study focuses specifically on learners’ perceived capability to perform English-speaking tasks with AI support.Their self-directed learning construct also addressed AI-supported learning more broadly, while AI-SRL in the present study is limited specifically to the regulation of AI-supported English-speaking practice. Being confident in using an AI tool is not necessarily the same as believing that one can perform a speaking task successfully. Likewise, general independent use of AI does not necessarily show how a learner plans, monitors, evaluates, and adjusts speaking practice.

Within the recent literature reviewed for the present study, direct quantitative evidence on the relationship between AI-supported self-regulated learning in speaking practice and speaking self-efficacy remains limited, particularly in Vietnamese university EFL contexts (Cong-Lem et al., 2025; Duong & Suppasetseree, 2024). The present study therefore focuses on this specific relationship rather than asking only whether students use AI or whether AI-

supported practice improves speaking performance, maintaining the critical distinction between technology usage and active self-regulatory control (Chang & Sun, 2024; Su et al., 2023). It examines how students report regulating their AI-supported speaking practice and whether this overall regulatory behaviour is associated with their beliefs about their capability to perform English-speaking tasks (Derakhshan & Fathi, 2024; Zimmerman, 2000).

The study was conducted with EFL students at a private university in Vietnam. It first examined students' reported levels of AI-SRL and speaking self-efficacy and then investigated the statistical relationship between the two constructs. Because the study employed a cross-sectional correlational design, it did not attempt to establish that one variable causes changes in the other (Creswell & Creswell, 2018; Slater & Hasson, 2025). The focus was limited to whether AI-SRL and speaking self-efficacy were associated and, if so, the direction and strength of that association (Field, 2024).

Accordingly, the study addressed the following research questions:

What are the reported levels of AI-supported self-regulated learning and speaking self-efficacy among EFL students at a private university in Vietnam?

Is there a statistically significant relationship between AI-supported self-regulated learning and speaking self-efficacy among these students?

2. Literature Review

2.1. Artificial Intelligence in Language Learning

Artificial intelligence has provided EFL learners with more opportunities for interaction, feedback, language production, and independent practice (Godwin-Jones, 2023; Kohnke et al., 2023; Lo, 2023). For speaking practice, two forms of technology are particularly relevant to the present study: generative AI and automated speech recognition (ASR). Generative AI can support interactive language practice by responding to learners' input, while ASR processes spoken language and provides information about learners' oral production (Kohnke et al., 2023; Sun, 2023). Both technologies can extend speaking practice beyond scheduled classroom interaction.

Recent studies have shown that AI-supported activities can be useful for speaking development. Fathi et al. (2024), for example, reported positive effects of AI-mediated interaction on EFL learners' speaking skills and willingness to communicate. ASR-supported practice has also been associated with improvements in pronunciation and speaking skills (Sun, 2023). These findings suggest that AI can provide useful conditions for repeated speaking practice. The availability of such opportunities, though, does not explain how learners actually use them.

Generative AI can support several parts of language practice, such as generating ideas, suggesting language, providing feedback, and creating conversational exchanges (Kohnke et al., 2023; Lo, 2023). Learners can also adjust prompts according to what they want to practise, which gives them some control over the direction of an activity. This flexibility may be useful when preparing for presentations, interviews, discussions, or other speaking situations. AI-supported practice is therefore less fixed than many traditional materials, but its learning value may still depend on the learner's level of engagement.

The availability of AI does not necessarily mean that learners regulate their learning actively (Chang & Sun, 2024; Hou & Zhou, 2025). Recent research on AI-supported language learning shows that self-regulated engagement involves processes such as goal setting, strategic

use of learning resources, monitoring, and reflection (Chang & Sun, 2024; Hou & Zhou, 2025). These processes require learners to make decisions about how AI is used and how information from the tool is incorporated into later learning (Hou & Zhou, 2025). For the present study, this distinction is important because AI use and AI-supported self-regulation are treated as related but different aspects of learning.

ASR can provide learners with information about their spoken production through speech recognition and transcription (Sun, 2023). Sun (2023) found that ASR-supported practice, combined with peer correction, contributed to improvements in EFL learners' pronunciation and speaking skills. During the intervention, learners reviewed ASR transcriptions, identified possible problems in their spoken production, and used this information during later practice (Sun, 2023). This process gave learners opportunities to notice aspects of their speech that required further attention. For the present study, ASR is therefore relevant as a source of performance information that learners may use during self-regulated speaking practice.

AI-supported speaking may also influence learners' affective experience during oral communication. Zhang et al. (2024) found that an AI-speaking assistant was associated with increased willingness to communicate and reduced foreign language anxiety among Chinese EFL university students. Wang et al. (2024) reported a similar pattern for a conversational GenAI chatbot with human-like avatars, with significant improvement in willingness to communicate and self-perceived communicative competence, together with lower foreign language speaking anxiety. These findings suggest that some AI-mediated speaking environments may provide a more supportive setting for oral practice (Wang et al., 2024; Zhang et al., 2024). The effects, however, appear to depend on the form of AI-supported interaction rather than on AI use alone. Wang et al. (2024), for example, found different outcomes across chatbot conditions, and no significant differences in speaking performance were observed across the groups.

2.2. Self-Regulated Learning

Self-regulated learning (SRL) refers to the processes through which learners actively manage their learning in relation to particular goals (Panadero, 2017; Pintrich, 2000; Zimmerman, 2002). Zimmerman’s cyclical model, which provides the main SRL framework for the present study, conceptualises regulation through three interconnected phases: forethought, performance, and self-reflection (Zimmerman, 2000, 2002). Although these sources provide the foundational framework, the cyclical model continues to inform recent research on technology-enhanced and AI-supported language learning (Chang & Sun, 2024; Hou & Zhou, 2025; Pan et al., 2025).

SRL involves more than studying independently. Learners need to establish goals, select appropriate strategies, monitor their progress, evaluate outcomes, and adjust their approach when necessary (Pan et al., 2025; Zhang & Zou, 2024). Recent second-language research describes self-regulation as an active and adaptive process in which strategies are used in relation to particular learning goals and conditions rather than simply possessed by learners (Pan et al., 2025). The important issue is therefore not only whether learners know a particular strategy, but whether they can select and use it appropriately when responding to a specific learning task (Zhang & Zou, 2024).

Self-regulation may also vary according to the task and learning environment. Zhang and Zou (2024) emphasise the interaction among learners, strategies, tasks, and learning contexts in self-regulated second-language learning. Preparing a presentation, practising

pronunciation, and participating in spontaneous conversation, for example, may place different demands on planning, monitoring, strategy use, and feedback evaluation (Panadero, 2017; Zimmerman, 2002). Technology-enhanced SRL research similarly suggests that regulatory processes can vary according to the learning activity and the type of technological support available (Pan et al., 2025). SRL is therefore better understood as a context-sensitive learning process than as a fixed pattern of behaviour applied in the same way across all situations.

Within Zimmerman's model, the forethought phase occurs before or at the beginning of a learning activity (Zimmerman, 2000, 2002). Learners identify goals, consider task demands, and decide how they intend to approach the activity (Zimmerman, 2000, 2002). In speaking practice, this may involve identifying an aspect of speaking that needs attention and selecting a suitable activity or resource. The goal established at this stage provides a reference point for later monitoring and evaluation.

The performance phase concerns what learners do while carrying out the activity. This phase includes strategy use, attention, and monitoring of ongoing performance (Zimmerman, 2000, 2002). During speaking practice, learners may attend to pronunciation, fluency, lexical choice, or their ability to communicate an intended meaning. When they notice that a strategy or approach is not producing the intended result, they may need to make adjustments while the activity is still in progress.

The self-reflection phase follows the learner's experience of the task. Learners evaluate what occurred, interpret the outcome, and use this information when considering later learning activities (Zimmerman, 2000, 2002). Reflection gives the model its cyclical character because information from one learning attempt can influence planning and strategy selection in a later attempt. Recent research on AI-supported and technology-enhanced SRL continues to describe regulation in terms of connected processes involving planning, action, monitoring, evaluation, and later adjustment (Chang & Sun, 2024; Pan et al., 2025).

Technology can create additional opportunities for these processes while also increasing the number of decisions learners need to make. Pan et al. (2025) found that technology can function as a learning environment, a resource, or a means of supporting self-regulation in second-language learning. When AI is introduced into this process, learners may need to decide which tool or activity is appropriate for a particular goal, which feedback deserves attention, and how information produced by the technology should influence later practice. These decisions provide the basis for examining SRL specifically within AI-supported language learning.

2.3. AI-Supported Self-Regulated Learning

In the present study, AI-supported self-regulated learning (AI-SRL) refers to the application of self-regulatory processes when learners use AI resources to support their English-speaking practice. Recent research has described self-regulation in AI-supported language learning in terms of planning, strategy use, monitoring, reflection, and adjustment while learners interact with AI-supported resources (Chang & Sun, 2024; Hou & Zhou, 2025). AI-SRL is therefore not treated here as a separate learning theory. Rather, the term is used to describe how established SRL processes operate within AI-supported speaking practice.

Recent research provides support for examining learning in this way. Chang and Sun's (2024) systematic review showed that AI has been used to support different stages of self-regulated language learning and highlighted the role of strategic AI use within a cyclical learning process. Hou and Zhou (2025) similarly identified regulatory processes involving planning, strategy execution, monitoring, reflection, and technological adaptation among EFL

learners in AI-supported environments. Together, these studies suggest that understanding AI-supported learning requires attention not only to what technological tools can provide, but also to how learners make decisions while using them.

In AI-supported speaking practice, regulation can occur across different stages of learning. Before an activity, learners may establish a speaking goal and decide how an AI resource can support that goal. During practice, they may apply strategies, monitor their performance, and respond to information generated by the AI system. After the activity, they may evaluate the feedback and their own performance before deciding what should be addressed in a later attempt (Chang & Sun, 2024; Hou & Zhou, 2025). In this way, AI-supported practice can form part of a continuing regulatory cycle rather than a series of isolated interactions with technology.

The distinction between AI use and AI-SRL is therefore central to the present study. Two learners may use the same AI tool but manage their speaking practice differently. One learner may mainly request corrections or model answers, whereas another may establish a specific speaking goal, examine feedback, compare different attempts, and decide what to practise next. Frequency of AI use alone cannot indicate how actively a learner regulates the learning process. For this reason, AI-use background information and AI-SRL are treated separately in the present research.

Technology-enhanced language-learning research provides further support for this distinction. Pan et al. (2025) showed that technology can support SRL in several ways, including providing environments for practice, supporting strategy use, and creating opportunities for learners to monitor and regulate their learning. However, technological support does not represent a single form of self-regulation across all learning situations. Its role depends partly on how learners incorporate the available resources into their own regulatory processes.

Based on Zimmerman's cyclical framework and recent AI-supported language-learning research, AI-SRL in the present study is conceptually discussed in relation to processes such as planning, performance monitoring, feedback evaluation, reflection, and subsequent adjustment (Chang & Sun, 2024; Hou & Zhou, 2025). These processes provide a theoretical basis for the content of the AI-SRL questionnaire items. However, they are treated as conceptual aspects of AI-SRL rather than empirically confirmed dimensions in the present study. The primary descriptive and correlational analyses therefore examine AI-SRL as an overall construct rather than analysing individual SRL phases or regulatory processes separately.

2.4. Speaking Self-Efficacy

Speaking self-efficacy concerns learners' beliefs about their capability to perform particular English-speaking tasks (Bandura, 1997, 2006; Phipps, 2024). Self-efficacy refers to perceived capability rather than an objective measure of actual performance (Bandura, 1997, 2006). Recent L2 speaking research has also treated self-efficacy as learners' beliefs about their capability in specific aspects of speaking performance (Li & Zhang, 2023; Phipps, 2024). For the present study, this distinction is important because the questionnaire measures what students believe they can do in speaking situations rather than their objectively assessed speaking proficiency.

Perceived capability and actual speaking performance are therefore related but should not be treated as the same construct (Bandura, 1997, 2006; Li & Zhang, 2023). Learners may differ in how they judge their speaking capability even when their language performance is

relatively similar, since efficacy judgements are based on how individuals interpret their abilities and experiences (Bandura, 1997, 2006). Recent longitudinal evidence also shows that speaking-related self-efficacy can change over time. Li and Zhang (2023), for example, tracked speaking accuracy, fluency, and self-efficacy across six observations and found that self-efficacy for both accuracy and fluency developed over the course of online-supported learning. Phipps (2024) similarly examined changes in speaking self-efficacy among university EFL learners and its relationship with learners' causal attributions and satisfaction with speaking outcomes. These findings suggest that speaking self-efficacy is not simply a fixed judgement of ability; it can develop as learners gain and interpret further speaking experiences.

Self-efficacy is also task- and domain-specific rather than a general sense of confidence (Bandura, 1997, 2006). This specificity is reflected in recent speaking research. Li and Zhang (2023), for instance, measured self-efficacy for speaking accuracy and self-efficacy for speaking fluency separately, showing that efficacy beliefs can be examined in relation to particular aspects of oral performance. A learner may therefore judge their capability differently across speaking demands, such as producing accurate language, speaking fluently, delivering a prepared presentation, or responding spontaneously in a discussion (Bandura, 2006; Li & Zhang, 2023). In the present study, speaking self-efficacy is consequently treated as learners' perceived capability to perform the English-speaking tasks represented in the questionnaire rather than as general confidence in English.

Recent L2 speaking research also provides evidence for considering self-efficacy together with self-regulation. Derakhshan and Fathi (2024) examined growth mindset, self-efficacy, self-regulation, and L2 speaking performance among EFL learners. Their structural model showed a direct positive relationship between self-efficacy and L2 speaking performance, while self-regulation also played a mediating role in the model (Derakhshan & Fathi, 2024). The study did not examine AI-supported speaking practice, so its findings cannot be treated as direct evidence for the relationship investigated in the present study. Its relevance lies in showing that self-efficacy and self-regulation can operate within the same broader process of L2 speaking development.

Bandura's theoretical framework identifies four main sources from which efficacy beliefs may develop: mastery experiences, vicarious experiences, social persuasion, and physiological and affective states (Bandura, 1997, 2006). The influence of these sources depends partly on how individuals interpret the information arising from their experiences rather than on the experience alone (Bandura, 1997). These four sources are included here to explain the theoretical background of speaking self-efficacy, not as separate variables in the present study. The current study measures learners' overall beliefs about their speaking capability and does not examine the individual contribution of the four efficacy sources.

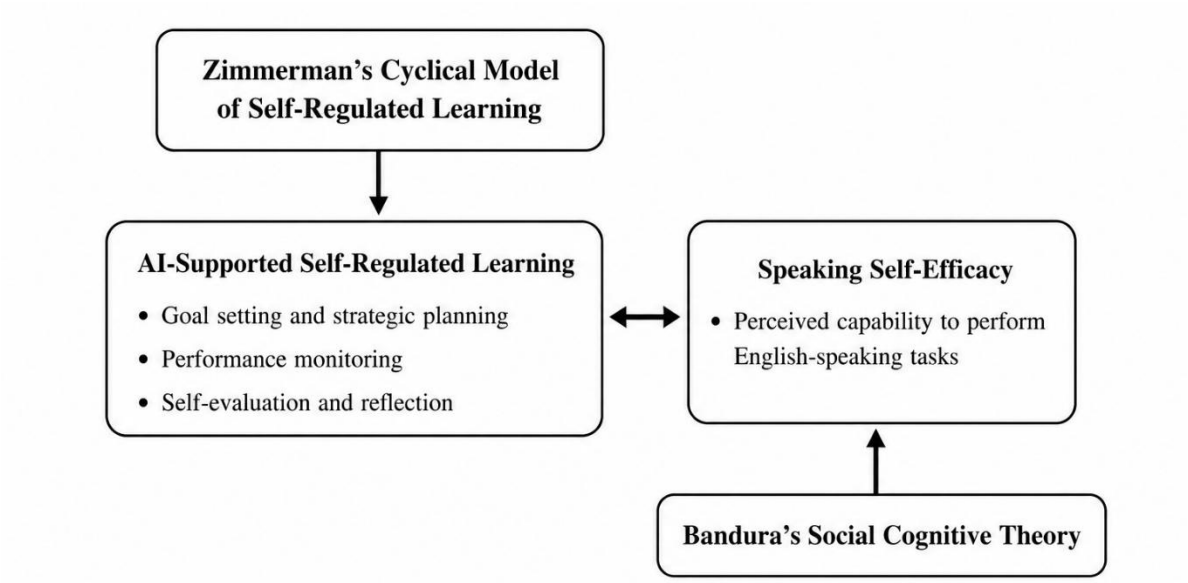
2.5. Linking AI-Supported Self-Regulated Learning and Speaking Self-Efficacy

AI-SRL and speaking self-efficacy represent conceptually different aspects of the learning process. AI-supported self-regulation concerns how learners plan, monitor, evaluate, and adjust their learning when AI resources are involved (Chang & Sun, 2024; Hou & Zhou, 2025), whereas speaking self-efficacy concerns learners' beliefs about their capability to perform particular speaking tasks (Li & Zhang, 2023; Phipps, 2024). Recent L2 speaking research has also examined self-efficacy and self-regulation within the same learning context, suggesting that the two constructs can be related while remaining theoretically distinct (Derakhshan & Fathi, 2024). For the present study, this distinction allows the relationship between learners' regulatory behaviour and their perceived speaking capability to be examined without treating them as the same construct.

Self-regulatory activities can provide learners with information about their performance and progress. Research on AI-supported SRL shows that monitoring and reflection allow learners to review learning processes, evaluate outcomes, and use information from earlier activity when making later decisions (Chang & Sun, 2024; Hou & Zhou, 2025). During AI-supported speaking practice, this may involve setting a goal, completing a speaking activity, examining feedback, comparing attempts, and deciding whether later practice needs to change (Chang & Sun, 2024; Hou & Zhou, 2025). Recent speaking research also shows that self-efficacy can develop over time alongside learners' speaking experiences and performance outcomes (Li & Zhang, 2023; Phipps, 2024). Information noticed during regulated practice may therefore become relevant when learners judge what they believe they can accomplish in later speaking tasks, although this possibility does not establish a causal effect of AI-SRL on speaking self-efficacy.

The connection may also be considered from the perspective of learners' existing efficacy beliefs. Recent L2 research has reported relationships among self-efficacy, self-regulation, and speaking performance, indicating that these learner factors can operate within the same broader speaking-learning process (Derakhshan & Fathi, 2024). Li and Zhang (2023) also found dynamic relationships between speaking self-efficacy and the development of speaking performance, while Phipps (2024) showed that speaking self-efficacy changed over time and was related to how learners interpreted speaking outcomes. These findings leave open the possibility that learners' existing beliefs about their speaking capability may be associated with how they approach and manage later practice. They do not, however, demonstrate that stronger self-efficacy causes stronger self-regulation.

The available literature therefore provides a theoretical and empirical basis for examining AI-SRL and speaking self-efficacy together, but it does not establish the direction of the relationship between them. The present study consequently treats their relationship as an association rather than a causal pathway. It does not propose that stronger AI-SRL causes stronger speaking self-efficacy or that higher speaking self-efficacy causes stronger AI-SRL. The empirical question is whether learners who report higher levels of AI-SRL also tend to report higher levels of speaking self-efficacy.



2.6. Theoretical Framework and Research Gap

The theoretical framework brings together Zimmerman's cyclical view of self-regulated learning and Bandura's concept of self-efficacy. Zimmerman's framework provides the theoretical basis for examining learners' planning, monitoring, evaluation, reflection, and adjustment of AI-supported speaking practice. Bandura's framework provides the basis for treating speaking self-efficacy as learners' perceived capability to perform speaking tasks. The two constructs remain separate, but both concern learner-related processes that may operate during speaking practice.

The relationship proposed in the present study is represented in Figure 1.

Figure 1

Theoretical Framework Linking AI-Supported Self-Regulated Learning and Speaking Self-Efficacy

Note. The double-headed arrow represents a theoretical and statistical association, not a causal pathway.

The double-headed arrow between AI-SRL and speaking self-efficacy represents the association examined in the present study rather than a causal relationship. The figure does not suggest that one construct produces changes in the other.

Studies of the use of AI in language learning have explored speaking performance, pronunciation, feedback, language anxiety, willingness to communicate, and learners' experiences of AI-mediated speaking practices (Fathi et al., 2024; Sun, 2023; Wang et al., 2024; Zhang et al., 2024). The study of language learning supported by AI and technology-enhanced language learning has also explored how learners plan, monitor, evaluate and reflect on their learning process with the presence of technological tools or resources (Chang & Sun, 2024; Hou & Zhou, 2025; Pan et al., 2025). A related line of L2 speaking research has considered self-efficacy in relation to speaking development, performance, and self-regulation (Derakhshan & Fathi, 2024; Li & Zhang, 2023; Phipps, 2024). These areas provide the main components of the present framework, but they have generally addressed different parts of the learning process rather than the specific relationship examined in this study.

This distinction becomes clearer when AI-supported speaking is considered. AI-mediated activities have been found to provide opportunities for speaking practice and to support aspects of speaking performance and willingness to communicate (Fathi et al., 2024; Sun, 2023). At the same time, research on AI-supported SRL shows that learners can engage in planning, strategy use, monitoring, and reflection while learning with AI (Chang & Sun, 2024; Hou & Zhou, 2025). Speaking research separately indicates that self-efficacy is related to learners' speaking development and performance (Derakhshan & Fathi, 2024; Li & Zhang, 2023; Phipps, 2024). What remains less clear is how these areas come together: specifically, whether learners who regulate their AI-supported speaking practice more strongly also tend to report stronger beliefs in their own speaking capability.

Recent research in Vietnam provides an important context for this question. Duong and Suppasetseree (2024) investigated an AI voice chatbot with Vietnamese undergraduate

students and found a significant improvement in English-speaking skills after an eight-week intervention. Their study focused primarily on speaking outcomes following AI-supported practice rather than on learners' self-regulation during that practice. Cong-Lem et al. (2025) examined another part of the issue by studying Vietnamese EFL learners' AI use, self-efficacy in using AI, and self-directed learning with AI. They reported a strong positive correlation between AI-use self-efficacy and self-directed learning with AI (r = .71, p < .001). These studies show that AI-supported language learning, learner beliefs, and learner-managed learning have already received attention in the Vietnamese EFL context, but the constructs examined are not identical to those in the present study.

The distinction between these constructs is important. AI self-efficacy concerns learners' confidence in their ability to use AI, whereas speaking self-efficacy concerns their perceived capability to perform English-speaking tasks (Cong-Lem et al., 2025; Li & Zhang, 2023; Phipps, 2024). Similarly, self-directed learning with AI covers learners' management of AI-supported learning more broadly, while AI-SRL in the present study is narrowed to the regulation of AI-supported English-speaking practice (Chang & Sun, 2024; Cong-Lem et al., 2025). A learner may therefore feel capable of using an AI tool without necessarily feeling equally capable of speaking English, and general independent use of AI does not necessarily describe how that learner regulates speaking practice.

Although the academic landscape has begun exploring educational technologies, direct quantitative research addressing the nexus between AI-supported self-regulated learning in speaking practice and speaking self-efficacy remains significantly limited especially within the context of Vietnamese higher education (Cong-Lem et al., 2025; Duong & Suppasetseree, 2024). Extant literature has individually probed adjacent areas such as AI-mediated speaking interventions (Duong & Suppasetseree, 2024), technology-supported self-regulation (Chang & Sun, 2024), L2 speaking self-efficacy (Derakhshan & Fathi, 2024), and broader self-directed AI usage (Cong-Lem et al., 2025); however, a critical research gap persists regarding how these distinct constructs interact in speaking practice. Consequently, the current study seeks to bridge this gap by investigating the extent to which EFL learners' strategic regulation of their AI-supported oral practice predicts their perceived capability to execute English-speaking tasks

The study examines the reported levels of AI-SRL and speaking self-efficacy and the statistical relationship between the two constructs among EFL students at a private university in Vietnam, aligning with emerging research on technology-mediated language learning in the local context (Cong-Lem et al., 2025; Duong & Suppasetseree, 2024). AI utilization is described separately and is not included as part of the AI-SRL composite measure, maintaining the critical theoretical distinction between mere technology usage and active self-regulatory control (Chang & Sun, 2024; Lai & Gu, 2011; Tseng et al., 2006). The four sources of self-efficacy are included only as theoretical background and are not analysed as separate variables (Bandura, 2006). Similarly, the individual phases of self-regulation are not tested as separate predictors within the quantitative model (Zimmerman, 2000, 2002). Finally, because the study employs a cross-sectional correlational design, it does not test whether one construct causes changes in the other, in accordance with established methodological boundaries for non-experimental research (Creswell & Creswell, 2023; Slater & Hasson, 2025). By doing so, these boundaries keep the theoretical framework aligned with the descriptive and correlational analyses used in the present study."

3. Methodology

3.1. Research Design

This study adopted a cross-sectional quantitative correlational design to examine the relationship between AI-supported self-regulated learning (AI-SRL) and speaking self-efficacy among Vietnamese EFL university students. A quantitative approach was appropriate because both constructs were measured through structured questionnaire items and analysed statistically across the participant sample (Creswell & Creswell, 2023). Data were collected at a single point in time, and the correlational design was used to determine the direction, magnitude, and statistical significance of the relationship between the two constructs (Slater & Hasson, 2025).

The study did not manipulate learning conditions or assign participants to experimental and control groups. Its purpose was therefore not to determine whether AI-SRL produced changes in speaking self-efficacy, but to examine whether students who reported stronger regulation of their AI-supported learning also tended to report stronger beliefs in their English-speaking capability. Descriptive statistics were used to address the first research question, while Pearson's product–moment correlation was used to examine the relationship addressed in the second research question.

3.2. Research Setting and Participants

The study was conducted at a private university in Ho Chi Minh City, Vietnam, where English is taught as a foreign language. The institution offers English courses for students who are majors and students who are not majors in English, and the study included students with different academic backgrounds and years of study. The participants were chosen using a convenience sampling method due to its practicality in accessing students who have experience in learning English and practicing speaking with the assistance of AI.

Data were collected over a four-week period from March to April 2026. The questionnaire was administered online through Google Forms and distributed through the university's student communication channels and class groups. A total of 200 responses were initially obtained.

Before statistical analysis, the dataset was screened for incomplete responses and indicators of inattentive responding in accordance with recommendations for detecting low-quality survey data (Ward & Meade, 2023). Particular attention was given to invariant response patterns, or *straight-lining*, in which the same Likert-scale option was selected repeatedly across items that represented conceptually different statements. Such response patterns can indicate limited engagement with questionnaire content. Fourteen responses were excluded because of substantial missing data or clear evidence of invariant responding, leaving 186 valid responses for the final analysis.

The participants also filled out a questionnaire regarding gender, undergraduate degree, academic specialty, prior exposure to AI for language learning and the kind of AI tools they had used. These variables were collected to describe the sample and provide contextual information about participants' experience with AI-supported learning. Not used as independent variables in main correlational analysis.

Because participants were recruited from a single private university through convenience sampling, the sample was not treated as representative of all Vietnamese university EFL learners. The findings were therefore interpreted within the institutional and educational context in which the data were collected.

3.3. Research Instrument

Data were collected using a structured self-report questionnaire consisting of three sections: demographic and AI-use background information, AI-supported self-regulated learning, and speaking self-efficacy.

The first section collected information on participants' gender, year of study, academic major, prior use of AI for English learning, and the types of AI tools they had used. These questions served a descriptive purpose only. They were not combined into an AI-use scale or treated as an additional construct in the inferential analysis.

The second section comprised 13 items measuring AI-supported self-regulated learning. The items were developed or adapted with reference to Zimmerman's (2000, 2002) cyclical model of self-regulated learning and were contextualised for AI-supported English-speaking practice. The initial theoretical structure reflected three related regulatory phases: forethought, performance, and self-reflection.

Forethought items addressed goal setting and strategic planning before speaking practice. Performance items focused on self-monitoring, strategy use, attention, and adjustment during AI-supported practice. Self-reflection items concerned the evaluation of performance, interpretation of feedback, and use of previous practice to inform subsequent learning decisions (Zimmerman, 2000, 2002). This structure allowed AI-SRL to be measured in terms of learners' regulatory behaviour rather than simply their frequency of AI use.

Participants rated each AI-SRL item on a five-point Likert-type scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). Higher scores indicated stronger reported engagement in AI-supported self-regulated learning.

The third section contained 12 items measuring speaking self-efficacy. The items were developed in accordance with Bandura's (2006) recommendations for constructing domain-specific self-efficacy measures and were contextualised for English-speaking tasks. They assessed learners' perceived capability to express ideas, respond to questions, maintain conversations, communicate despite linguistic difficulties, and perform oral tasks under different conditions.

The speaking self-efficacy items used the same five-point Likert-type response format. Higher scores represented stronger perceived capability to perform English-speaking tasks. Consistent with Bandura's (2006) task-specific conceptualisation of self-efficacy, the scale was designed to measure perceived speaking capability rather than related constructs such as speaking anxiety, willingness to communicate, persistence, or actual speaking proficiency.

Before the main data collection, the questionnaire was piloted with 20 undergraduate students who were not included in the final sample. The pilot was used to examine item clarity, response-format appropriateness, and the approximate time required for completion. Minor revisions were made to improve wording before the questionnaire was distributed to the main sample.

The full item sets were retained at the initial measurement stage. Their psychometric properties were subsequently examined before the final construct scores were calculated.

3.4. Data Collection and Analysis Procedure

Google Forms were used to conduct the questionnaires online. This was self-administered and answers were typed in from the participants. The data was then exported to IBM SPSS Statistics 26 for screening and statistical analysis. The first set of data had 200

answers. Following the above screening process, 14 responses were eliminated, with 186 cases analyzed.

The initial dataset contained 200 responses. After the screening procedure described above, 14 responses were removed, leaving 186 cases for analysis. The remaining data were examined for incomplete responses, coding errors, values outside the permitted response range, and potential response-quality problems. Before Pearson's correlation was calculated, the distributions of the two main variables were also inspected for influential outliers, approximate normality, and linearity because substantial violations of these conditions can affect the interpretation of a Pearson correlation coefficient (Field, 2024).

Descriptive statistics were first calculated to address Research Question 1. Means and standard deviations were used to describe participants' reported levels of AI-SRL and speaking self-efficacy. Demographic information and AI-use background variables were used only to characterise the sample and were not entered into the primary inferential analysis.

Exploratory factor analysis (EFA) was conducted for the AI-SRL scale because the items had been contextualised specifically for AI-supported English-speaking practice. Principal Axis Factoring was used as the extraction method because the purpose was to examine the latent structure underlying the items rather than simply reduce the number of observed variables. Direct Oblimin rotation was selected because the proposed dimensions of self-regulation were theoretically expected to be related rather than independent (Hair et al., 2019).

Before factor extraction, sampling adequacy and factorability were assessed using the Kaiser–Meyer–Olkin (KMO) measure and Bartlett's test of sphericity. Factor-retention decisions considered several sources of evidence, including eigenvalues, the scree plot, factor-loading patterns, and the theoretical interpretability of the extracted solution (Hair et al., 2019). Statistical criteria were therefore considered alongside the theoretical structure of SRL rather than used in isolation.

The speaking self-efficacy scale was treated as a single task-specific construct in accordance with the conceptualisation adopted in the study and Bandura's (2006) approach to domain-specific self-efficacy measurement. Its measurement quality was therefore assessed primarily through internal consistency rather than through a separate exploratory factor analysis.

Cronbach's alpha was calculated for both the AI-SRL and speaking self-efficacy scales. Coefficients of .70 or above were regarded as generally acceptable for research purposes (Nunnally & Bernstein, 1994). Corrected item–total correlations and changes in alpha following item deletion were also examined. Item-retention decisions were not based solely on whether deleting an item produced a higher alpha value; theoretical relevance, construct coverage, and consistency with the intended meaning of the scale were also considered.

After factor structure and internal consistency had been evaluated, the retained items for each construct were averaged to produce composite scores. Averaging preserved the original five-point response metric, with higher scores representing stronger AI-SRL or speaking self-efficacy. Construct-level scores were used in the main analyses because the research questions concerned the overall levels of the two constructs and the relationship between them.

Pearson's product–moment correlation coefficient was then calculated to address Research Question 2. The analysis examined the direction, magnitude, and statistical

significance of the relationship between AI-SRL and speaking self-efficacy. A two-tailed test was conducted and a p value less than .05 was considered statistically significant. Cautious interpretation of correlation coefficients was done in consideration of Cohen's (1988) conventional cut-off points of approximately .10, .30 and .50 for small, moderate and large associations, respectively. The values were used as general guidelines for interpreting, not as cut-off points. The results of the coefficient were also judged for their statistical significance in the same direction and with the same size. The study was of a cross sectional correlational design and therefore the correlation was seen as a statistical association, not a cause effect. This distinction determined the way the results were reported and discussed.

3.5. Ethical Considerations

Ethical considerations were incorporated throughout the data-collection process. Before completing the questionnaire, participants received information about the purpose of the study, the voluntary nature of participation, and the confidentiality of their responses. They were also informed that their decision to participate or decline participation would have no effect on their academic standing.

Participants could discontinue the questionnaire at any point before submitting their responses. No personally identifying information was included in the statistical analyses or reported in the study. The data were used solely for research purposes, and all findings were presented in aggregate form to protect participant confidentiality.

4. Results

4.1. Reliability Analysis

Before the main statistical analyses, the reliability of the two adapted scales was examined using Cronbach's alpha. The 13-item AI-Supported Self-Regulated Learning (AI-SRL) scale produced an alpha of .808, while the 12-item Speaking Self-Efficacy scale produced an alpha of .832. Both values indicated acceptable internal consistency, so the two scales were retained for the following analyses.

Table 1

Reliability coefficients of the psychological scales used in this study.

Scale	Number of Items	Cronbach's Alpha
AI-Supported Self-Regulated Learning	13	.808
Speaking Self-Efficacy	12	.832

More detailed reliability results are provided in Appendices A and B. All items in the Speaking Self-Efficacy scale had corrected item-total correlations above .30. For the AI-SRL scale, one item, SRL_F3, showed a lower corrected item-total correlation of .193. Removing this item would have increased Cronbach's alpha only slightly, from .808 to .815. The item was kept because it represented a theoretically relevant part of the AI-SRL construct. Its weaker performance at the item level, though, suggests that it may need further review in future validation studies.

Reliability was not calculated for the AI Utilization section. The items in this section were intended to describe different patterns and purposes of AI use rather than measure a single underlying construct. Calculating one Cronbach's alpha value for these items would therefore not have been suitable.

To examine the internal structure of the adapted AI-SRL scale, an exploratory factor analysis (EFA) was also conducted using Principal Axis Factoring. The Kaiser-Meyer-Olkin (KMO) value was .773, while Bartlett's test of sphericity was statistically significant, $\chi^2(78) = 677.297$, $p < .001$. These results indicated that the data were suitable for factor analysis.

As reported in Table 2, the extracted solution explained 40.04% of the total variance. The observed factor pattern, however, did not clearly reproduce the three proposed dimensions of forethought, performance, and self-reflection.

Table 2

Exploratory factor analysis results for the AI-supported self-regulated learning scale

Statistic	Value
KMO	.773
Bartlett's χ^2	677.297
df	78
Sig.	< .001
Total Variance Explained	40.04%

The EFA therefore offered only preliminary support for the internal structure of the adapted AI-SRL scale. At the same time, the scale showed acceptable internal consistency, with Cronbach's alpha of .808. For this study, the AI-SRL items were therefore retained as a composite measure for the descriptive and correlational analyses. The results involving AI-SRL should still be interpreted with some caution, as the proposed dimensional structure was not clearly reproduced in the EFA. Further validation with larger and more diverse samples would help determine whether the three-dimensional structure can be supported more clearly.

4.2. Descriptive Statistics

Descriptive statistics were calculated to examine the reported levels of AI-supported self-regulated learning and speaking self-efficacy among the participants. As presented in Table 3, the mean score for AI-SRL was 3.65 (SD = 0.53), while the mean score for speaking self-efficacy was 3.62 (SD = 0.57).

Both mean scores were above the midpoint of the five-point response scale. This indicates that participants generally reported favourable levels of self-regulation while using AI and favourable beliefs about their capability to perform English-speaking tasks.

Table 3

Descriptive Statistics for the Main Variables

Variable	N	Min	Max	M	SD
AI-Supported Self-Regulated Learning (AI-SRL)	186	2.08	5.00	3.65	0.53
Speaking Self-Efficacy	186	2.00	5.00	3.62	0.57

AI-SRL produced a slightly higher mean score than speaking self-efficacy. However, the difference between the two descriptive means was small and was not subjected to inferential comparison because the study did not aim to test differences between the constructs. The

speaking self-efficacy score should be interpreted as participants' perceived capability to perform the speaking tasks represented in the questionnaire rather than as evidence of their objectively assessed speaking proficiency.

4.3. Correlation Analysis

Pearson's product–moment correlation analysis was conducted to examine the relationship between AI-supported self-regulated learning and speaking self-efficacy.

As presented in Table 4, a statistically significant moderate positive correlation was found between AI-SRL and speaking self-efficacy, $r = .458$, $p < .001$. This result indicates that participants who reported stronger self-regulation while using AI also tended to report stronger beliefs in their capability to perform English-speaking tasks.

Table 4

Pearson correlation between AI-supported self-regulated learning and speaking self-efficacy

Variables	1	2
1. AI-supported self-regulated learning	—	.458**
2. Speaking self-efficacy	.458**	—

Note. $N = 186$. p < .01, two-tailed.

The result answered the second research question by demonstrating a statistically significant positive association between the two constructs. However, the correlation does not establish causal direction. It cannot be concluded that stronger AI-SRL caused higher speaking self-efficacy or that stronger speaking self-efficacy caused greater self-regulation. The finding indicates only that the two variables were positively associated within the present sample.

5. Findings and Discussion

5.1. Summary of Findings

The present study examined the reported levels of AI-supported self-regulated learning (AI-SRL) and speaking self-efficacy among 186 Vietnamese EFL university students and investigated the relationship between the two constructs. The findings showed that participants generally reported engagement in AI-supported regulatory practices, including goal setting, strategic planning, performance monitoring, feedback evaluation, and self-reflection. They also reported relatively positive beliefs about their capability to perform English-speaking tasks. These results describe how participants perceived their own learning behaviours and speaking capability rather than how effectively they actually regulated their learning or performed in spoken English.

The correlation analysis identified a statistically significant positive relationship between AI-SRL and speaking self-efficacy. Students who reported stronger regulation of their AI-supported learning also tended to perceive themselves as more capable of performing English-speaking tasks. The relationship is therefore meaningful at the level of reported regulatory behaviour and perceived capability within this sample. Its interpretation does not extend to actual speaking proficiency or to changes in either construct over time.

5.2. Discussion of the Findings

Participants generally reported engaging in regulatory behaviours when they used AI to support their English learning. Their responses indicated involvement in planning, performance monitoring, feedback evaluation, reflection, and adjustment of subsequent

learning activities. Rather than portraying AI use as a largely passive activity, this pattern suggests that at least some of the students' reported engagement with AI involved decisions about what to practise, how to monitor progress, and what to do with the information produced during practice.

This pattern can be interpreted through Zimmerman's (2000, 2002) cyclical model of self-regulated learning. In that model, regulation develops through interactions among forethought, performance, and self-reflection rather than through isolated strategy use. The relevance of the model to the present finding lies in the way participants reported using AI across different stages of practice. Planning can give direction to an AI-supported activity, monitoring allows learners to compare ongoing performance with an intended goal, and reflection provides a basis for deciding what should be addressed next. AI-supported practice may provide resources for each of these processes, but the regulatory work remains with the learner.

Research on AI-supported language learning provides related evidence for this interpretation. AI tools can generate practice activities, provide feedback, and give learners opportunities to inspect and revise their language (Kohnke et al., 2023; Su et al., 2023). These technological functions are relevant to the present result because they create opportunities for the types of planning, monitoring, and evaluation reported by participants. The availability of such functions, however, does not establish that learners use them strategically. What distinguishes AI-SRL from AI use more generally is the learner's active evaluation of the information provided and the decisions made on the basis of that information.

The reported level of AI-SRL should therefore be interpreted within the limits of the measurement used in this study. Participants described their own regulatory behaviour; the questionnaire did not directly observe how they interacted with AI or determine whether the feedback they received was accurate. Pintrich (2000) and Zimmerman (2002) both place learner judgement and strategic adaptation at the centre of self-regulation. From this perspective, the present result indicates that participants perceived themselves as engaging in regulatory processes, rather than demonstrating that every instance of their AI use was purposeful or effective.

Reported Level of Speaking Self-Efficacy

Participants also reported relatively positive perceptions of their capability to perform English-speaking tasks. This finding concerns speaking self-efficacy, not objectively assessed speaking proficiency. The distinction matters because students were asked to judge what they believed they could do in speaking situations rather than demonstrate their speaking ability through a performance assessment.

Bandura's (1997, 2006) conceptualisation of self-efficacy provides a useful basis for interpreting this result. Self-efficacy reflects perceived capability for particular tasks and develops partly through the way individuals interpret their previous experiences. Two learners with comparable language proficiency may therefore evaluate their speaking capability differently. In the present context, participants' responses may reflect how they interpreted previous speaking experiences, feedback, perceived progress, and the difficulty of the speaking situations they had encountered.

Bandura (1997) identifies mastery experiences, vicarious experiences, social persuasion, and physiological and affective states as sources from which efficacy information can be derived. These sources offer a theoretical explanation for why speaking self-efficacy may differ across learners even when they study in similar educational settings. A learner who

interprets repeated speaking attempts as evidence of progress, for example, may judge a subsequent task differently from a learner who interprets similar difficulties as evidence of limited capability. The present study did not measure these four sources separately, so they provide an explanatory framework rather than an empirical explanation tested by the current data.

Previous language-learning research also suggests that speaking-related efficacy beliefs are connected with how learners approach oral tasks. Asakereh and Nouraee (2018) linked self-efficacy beliefs with speaking fluency, while Raoofi et al. (2012) examined self-efficacy alongside metacognitive processes and English-speaking performance. These studies offer related evidence rather than a direct comparison with the present finding because the constructs and outcomes examined are not identical. Their relevance lies in showing that learners' judgements of speaking capability form a meaningful part of the broader speaking-learning process.

The participants' reported self-efficacy should consequently not be taken as evidence that they possessed an equivalent level of speaking competence. Bandura (1997, 2006) distinguishes efficacy judgements from actual performance, and the present study maintained that distinction in both measurement and interpretation. What the finding captures is how capable these students believed themselves to be, which is theoretically meaningful but not interchangeable with demonstrated speaking ability.

Relationship Between AI-Supported Self-Regulated Learning and Speaking Self-Efficacy

The principal finding was a statistically significant positive relationship between AI-SRL and speaking self-efficacy. Students who reported stronger planning, monitoring, feedback evaluation, and reflection in their AI-supported learning also tended to report stronger beliefs in their capability to perform English-speaking tasks. The two constructs therefore tended to vary in the same direction within this sample.

Zimmerman's (2000, 2002) model of SRL and Bandura's (1997, 2006) account of self-efficacy offer complementary explanations for why such an association is theoretically plausible. Self-regulated learners establish goals, monitor progress, evaluate outcomes, and use information from previous attempts when deciding how to proceed. Bandura's framework, meanwhile, proposes that efficacy judgements are informed partly by how individuals interpret experiences and performance-related information. The conceptual point of connection lies in this process of interpretation: regulatory activities can make information about progress, difficulty, and strategy effectiveness more available to learners, while efficacy beliefs concern what learners make of their capability in light of such experiences.

Consider a learner who establishes a specific speaking goal and compares several attempts while practising with AI. Monitoring may make gradual changes in pronunciation, fluency, lexical choice, or communicative effectiveness easier for that learner to notice. Feedback evaluation and reflection can then help the learner decide whether those changes represent progress and what requires further attention. Such experiences could become relevant to efficacy judgements when learners interpret them as information about what they are capable of accomplishing. This explanation remains theoretical, since the present study did not directly observe the interpretive process through which individual efficacy judgements developed.

Related language-learning research has connected self-efficacy with performance across various language skills and tasks. Reviewing 32 empirical studies, Raoofi et al. (2012) concluded that self-efficacy was a strong predictor of second- and foreign-language

performance. However, relatively few studies have specifically examined speaking self-efficacy (Phipps, 2024). These studies do not directly test the relationship between AI-SRL and speaking self-efficacy, so they should not be treated as direct empirical confirmation of the present result. Instead, they provide related evidence that capability beliefs can be connected with the regulatory and performance dimensions of language learning. The present study extends the question into the more specific setting of AI-supported speaking practice.

The association may also be understood from the other direction. Bandura (1997) associates stronger efficacy beliefs with goal choice, effort, and persistence, while Zimmerman (2000) places self-efficacy among the motivational processes involved in self-regulated learning. Students who already perceive themselves as more capable speakers may therefore be more willing to establish goals, continue practising when difficulties arise, or engage actively with feedback. The present data cannot distinguish this possibility from the alternative explanation in which stronger regulation is associated with the development of stronger efficacy beliefs.

For that reason, the positive correlation should be interpreted as evidence that AI-SRL and speaking self-efficacy co-occurred systematically within the present sample. It does not identify which construct precedes the other or whether a third factor contributes to both. Longitudinal or experimental research would be needed to examine temporal ordering or causal mechanisms. Within the boundaries of the current design, the finding establishes a statistical relationship and provides a basis for investigating how regulation and perceived speaking capability may interact over time.

5.3. Pedagogical Implications

The findings suggest that pedagogical attention to AI-supported speaking practice should extend beyond access to technological tools. Because stronger reported AI-SRL was associated with stronger speaking self-efficacy, students may benefit from learning how to organize AI-supported practice around explicit goals, monitoring, feedback evaluation, and reflection. This recommendation follows from the observed relationship and the theoretical framework; it should not be interpreted as evidence that SRL instruction will necessarily produce stronger efficacy beliefs.

For students, purposeful AI-supported practice can begin with a clearly defined speaking objective. A learner might focus on fluency, pronunciation, lexical choice, or the ability to respond spontaneously rather than simply asking an AI system to “practice English.” During the activity, learners can monitor the aspect of performance connected with that goal and record difficulties that require further attention. Afterward, they can evaluate the feedback received and decide what should change in the next attempt. This structure keeps decision-making with the learner rather than allowing the technological tool to determine the direction of practice.

Critical evaluation is particularly important because AI feedback is not uniformly reliable. Generative AI may produce inaccurate or contextually inappropriate information, while ASR systems can respond inconsistently to some accents and pronunciation patterns (Kohnke et al., 2023; McCrocklin, 2016). These limitations mean that students need criteria for deciding when feedback is useful and when it should be checked against teacher guidance, task requirements, or other reliable language resources. Developing this judgement is part of learning to use AI strategically rather than merely frequently.

Teachers can support the same process by designing AI-assisted speaking activities around a regulatory cycle. Before practice, students can identify a goal and explain why a

particular AI-supported task is suitable for it. During the activity, attention can be directed toward a limited aspect of performance rather than toward every possible language problem at once. Reflection after the task can then focus on what changed, which feedback was useful, and what should be addressed in the next attempt. This sequence corresponds with the forethought, performance, and self-reflection phases described by Zimmerman (2000, 2002), while still allowing teachers to adapt activities to different speaking objectives.

Frequent AI use should not, in itself, be taken as evidence of strategic learning. Two students may spend comparable amounts of time using the same tool while making very different decisions about goals, feedback, and revision. Classroom tasks can make these decisions visible by asking learners to explain why they selected an activity, which feedback they accepted or rejected, and how they modified subsequent practice. Such requirements place emphasis on the learning process rather than on technology use as an outcome in its own right.

At the curriculum and institutional levels, AI-supported speaking activities can be embedded within structured learning cycles rather than introduced as isolated technology-based tasks. Teacher professional development can similarly address both the pedagogical use of AI and the limitations of AI-generated feedback. Issues such as learner dependence, academic integrity, feedback accuracy, and responsible use remain relevant when AI becomes part of independent language practice. The practical implication of the present findings is therefore not that more AI use is necessarily desirable, but that the quality of learner regulation deserves attention alongside technological access.

5.4. Limitations and Recommendations for Future Research

Several limitations define the scope within which these findings should be interpreted. The first concerns the cross-sectional correlational design. Because both constructs were measured at one point in time, the analysis cannot determine temporal ordering between AI-SRL and speaking self-efficacy. Longitudinal research could examine whether changes in one construct precede changes in the other, while experimental or quasi-experimental designs could test the effects of structured AI-SRL interventions. Such designs would address questions that the present correlational evidence cannot resolve.

A second limitation arises from the exclusive use of self-report questionnaire data. Participants may have overestimated or underestimated both their regulatory behaviour and their speaking capability, and measurement of the two constructs through the same response format may introduce common-method bias. Future research could combine questionnaires with learner journals, interviews, observations, AI interaction records, or learning analytics. Speaking assessments would add another useful source of evidence because they would allow perceived capability to be examined alongside demonstrated performance.

This distinction is especially relevant to speaking self-efficacy. The present study measured what learners believed they could accomplish in English-speaking tasks rather than how proficiently they actually performed those tasks. Future studies could examine AI-SRL, speaking self-efficacy, and independently assessed speaking performance within the same design. Such evidence would make it possible to investigate the extent to which learners' efficacy judgements correspond with observable speaking performance.

Measurement of AI-SRL also warrants further investigation. The scale was adapted specifically for AI-supported English-speaking practice, and although its reliability and internal structure were examined, the exploratory factor analysis did not fully reproduce the proposed multidimensional structure. Future studies could refine individual items and test the revised scale with larger and more diverse samples before using confirmatory factor analysis

to evaluate the proposed structure. Further validation would strengthen the distinction between the theoretical organisation of AI-SRL and its empirical measurement.

The sample places an additional boundary on interpretation. The experiences of all participants may differ from those of learners at public institutions, universities in other parts of Vietnam, and programmes that have different language requirements or technological resources. The research might be multi-institutional to explore the possibility that similar patterns emerge in other disciplines, in other regions, at different proficiency levels, and in different institutions. A wider sampling of data would give better grounds for determining the extent of context in which the observed relationship might be seen. Last, overall level of AI-SRL and speaking SE was analyzed. It did not employ individual SRL phases, Bandura's four sources of self-efficacy, the specific AIs or mediating and moderating variables. Future studies might examine the relationship between goal setting, monitoring, and reflection with speaking self-efficacy and determine if any other variables, including AI competence, digital literacy, language proficiency, language motivation or language anxiety, explain variation in that relationship. This work would not only be a determination of the constructs' association but an attempt to explain when and how they are associated.

6. Conclusion

The present study focused on the level of self-efficacy in speaking and the presence of AI-supported self-regulated learning (AI-SRL) among 186 Vietnamese university students learning English as a foreign language (EFL), and explored the relationship between these two constructs. The participants' self-efficacy in AI-SRL and speaking was relatively high, and the analysis found that there was a significant positive correlation between AI-SRL and speaking. Those students who reported higher levels of consistency across all five categories of goal setting, strategic planning, performance monitoring, evaluating feedback and self-reflection in relation to using AI were also more likely to feel capable of performing English-speaking tasks.

The observed relationship can be understood in the complementary viewpoints of self-regulated learning and self-efficacy.. Zimmerman’s (2000, 2002) cyclical model positions goal setting, monitoring, and reflection as processes through which learners manage and adapt their learning, whereas Bandura’s (1997) social cognitive theory explains how learners form judgements about their capability from interpreted experiences and performance-related information. Considered together, these perspectives provide a theoretical basis for understanding why regulatory behaviour and speaking-related efficacy beliefs may be connected in AI-supported learning. The present evidence establishes this connection at the level of statistical association, not causal influence.

The study adds context-specific evidence from Vietnamese higher education by examining AI-supported self-regulation and speaking self-efficacy within the same empirical framework. Its contribution lies partly in shifting attention away from AI access or frequency of use toward the way learners manage AI-supported practice. From this perspective, educational value is not located in the technology alone. It also relies on whether the learners are able to define goals, self monitor their performance, assess technological feedback and choose further practice. The implication for speaking instruction using artificial intelligence is that it is necessary to implement this interpretation in practice. Giving students access to generative AI or speech technologies alone is not enough, and may not be designed to help them use the technology purposefully. Goal setting, strategic practice, monitoring, critical feedback evaluation, and reflection can then be incorporated into AI-enabled speaking activities for teachers. This kind of support can help to shift the narrative about AI from the idea of a pre-packaged answer to a tool for learners to use.

The conclusions, however, are limited by the design of the study. This study used a cross sectional correlational design, self-reported data, and participants from only one private university and cannot establish the temporal or causal direction between AI-SL and speaking SE. Future studies could build on this research by employing longitudinal and experimental designs, samples from a wider range of institutional settings, and mixed-methods studies that incorporate speaking proficiency along with learner reflections and/or accounts of real-time, AI-supported speaking practice. This evidence would facilitate an understanding not only of the relationship between the two constructs, but also how that relationship changes within learners, across tasks and educational contexts..

Bionote

Hoang The Hai Nguyen is currently pursuing a master's degree in English Language at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). His research interests include technology-enhanced language learning, artificial intelligence in English education, self-regulated learning, and EFL speaking development.

Appendix: Questionaire

Title: Examining the Relationship between AI-Supported Self-Regulated Learning and Speaking Self-Efficacy among Vietnamese EFL University Students

Description: This questionnaire aims to explore how students use AI tools in their English speaking practice and how confident they feel about their speaking ability. Your responses are anonymous and will be used for research purposes only. There are no right or wrong answers.

PART A. BACKGROUND INFORMATION

1. Gender:

[ ] Male

[ ] Female

2. Year of study:

[ ] First year

[ ] Second year

[ ] Third year

[ ] Fourth year

3. Major:

[ ] English major

[ ] Non-English major

4. Have you ever used AI tools for learning English?

[ ] Yes

[ ] No

5. Which AI tools have you used for learning English? *(Select all that apply)*

[ ] ChatGPT/Gemini

[ ] ELSA Speak/DuoLingo

[ ] Google Translate

[ ] Others

PART B. AI USAGE

Scale: 1 = Never, 2 = Rarely, 3 = Sometimes, 4 = Often, 5 = Very often

1. I use AI tools to generate ideas before speaking. [1] [2] [3] [4] [5]
2. I use AI tools to learn vocabulary or expressions for speaking. [1] [2] [3] [4] [5]
3. I use AI tools to practice pronunciation. [1] [2] [3] [4] [5]
4. I use AI tools to improve my fluency. [1] [2] [3] [4] [5]
5. I use AI tools to receive feedback on my speaking. [1] [2] [3] [4] [5]
6. I use AI tools to simulate conversations. [1] [2] [3] [4] [5]

7. I use AI mainly for translation instead of speaking practice. [1] [2] [3] [4] [5]
8. I use AI mainly to get ready-made answers. [1] [2] [3] [4] [5]
9. I use AI tools to repeat speaking practice many times. [1] [2] [3] [4] [5]
10. I use AI tools because they make speaking practice less stressful. [1] [2] [3] [4] [5]

PART C. AI-SUPPORTED SELF-REGULATED LEARNING (SRL)

Scale: 1 = Strongly disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly agree

C1. Forethought – Goal Setting & Planning

1. I set clear speaking goals before using AI tools. [1] [2] [3] [4] [5]
2. I decide which speaking skills I want to improve. [1] [2] [3] [4] [5]
3. I plan how I will practice speaking with AI tools. [1] [2] [3] [4] [5]
4. I choose AI tools based on my learning goals. [1] [2] [3] [4] [5]

C2. Performance – Monitoring & Control

1. I monitor my speaking performance while using AI. [1] [2] [3] [4] [5]
2. I pay attention to AI feedback. [1] [2] [3] [4] [5]
3. I try to correct my mistakes during practice. [1] [2] [3] [4] [5]
4. I adjust my speaking based on AI feedback. [1] [2] [3] [4] [5]
5. I actively interact with AI instead of copying answers. [1] [2] [3] [4] [5]

C3. Self-Reflection – Evaluation & Reflection

1. I evaluate my speaking after using AI tools. [1] [2] [3] [4] [5]
2. I reflect on my mistakes. [1] [2] [3] [4] [5]
3. I think about how to improve in future practice. [1] [2] [3] [4] [5]
4. I compare my progress over time. [1] [2] [3] [4] [5]

PART D. SPEAKING SELF-EFFICACY

Scale: 1 = Strongly disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly agree

D1. Confidence

1. I am confident in my ability to speak English. [1] [2] [3] [4] [5]
2. I can express my ideas clearly in English. [1] [2] [3] [4] [5]
3. I can communicate effectively in conversations. [1] [2] [3] [4] [5]

D2. Willingness to Communicate

1. I am willing to start a conversation in English. [1] [2] [3] [4] [5]
2. I am willing to speak with strangers. [1] [2] [3] [4] [5]
3. I actively participate in speaking activities. [1] [2] [3] [4] [5]

D3. Persistence

1. I can continue speaking even when I make mistakes. [1] [2] [3] [4] [5]

2. I keep trying even when speaking is difficult. [1] [2] [3] [4] [5]

3. I do not give up easily when I lack vocabulary. [1] [2] [3] [4] [5]

D4. Anxiety Control

1. I feel confident even when I am nervous. [1] [2] [3] [4] [5]

2. I am not afraid of making mistakes when speaking. [1] [2] [3] [4] [5]

3. I feel comfortable speaking in different situations. [1] [2] [3] [4] [5]

#44 Application of AI in Teaching and Learning Business English at HUFLIT: strengths, weaknesses, and solutions

Nguyen Thi Bach Yen [1]

Abstract

The research explores the effectiveness of applying Artificial Intelligence (AI) to the teaching and learning of Business English at HUFLIT, specifically in the Customer Service course. The writer uses action research through qualitative and quantitative data collection methods, such as, observation, interview, and survey. The participants include 420 juniors majoring in Business English of six Customer Service classes over a 12-week semester. The study findings show that AI enhances motivation, language use, and communication skills for students. Moreover, the findings show the dependence on AI of some students during the semester. In a nutshell, the research concludes that AI contributes to the teaching and learning of Business English courses positively and effectively with the clear instructions from the lecturers and the appropriate use of the students.

Keywords: Artificial Intelligence (AI), application, Business English, strengths, weaknesses, solutions

1. Introduction

The integration of Artificial Intelligence (AI) into education in general and in teaching and learning English specifically has emerged as a global trend these days. The integration of Computer-Assisted Language Learning (CALL) and Artificial Intelligence (AI) into English as a Foreign Language (EFL) instruction represents a pivotal shift in pedagogical paradigms, driven by the imperative to transcend traditional barriers to language acquisition and foster a more interactive, communicative, and learner-centered educational environment. This transition is necessitated by the evolving demands of the digital era, which calls for an educational approach that not only accommodates the diverse learning styles and needs of students but also leverages technological advancements to enhance teaching effectiveness and language learning outcomes (Hui-Chin, 2024). This trend is particularly relevant at the tertiary level, where both students and instructors often possess the foundational digital literacy required to adopt AI-enhanced methodologies effectively.

Vietnam is no exception to this global movement. In line with global trends, Vietnamese universities and colleges have started integrating AI into teaching and learning practices, especially in specialized fields such as Business English. At Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), this shift has been both timely and strategic. Located in Vietnam's economic and technological hub, HUFLIT benefits from strong infrastructural support, well-trained teaching staff, and a dynamic student population—all of which facilitate the effective adoption of AI-driven educational tools. Faculty members at HUFLIT have received institutional training on how to use AI in lesson planning, instruction, and assessment, significantly improving teaching efficiency while reducing the time spent on administrative tasks. Meanwhile, students are encouraged to use AI tools such as Magic School, ChatGPT, and Gemini to support their learning in Business English

[1] *Faculty of Foreign Languages, Ho Chi Minh University of Foreign Languages - Information Technology (HUFLIT); Email: yenntb@huflit.edu.vn*

courses like Customer Service, Advertising and Marketing, Negotiation Skills, and Marketing in Business.

Despite these advantages, several academic pressures have emerged over the past two years that hinder student learning. Most notably, the academic program has been condensed from four years to three and a half, while the academic calendar has been expanded from two semesters to three per year. These structural changes have led to course overload, leaving students with little time to absorb knowledge, reflect critically, or engage meaningfully with the material. Moreover, some lecturers worried about the abuse of AI from students leading to low results in learning. Therefore, not all lecturers in HUFLIT accept using AI in students' learning process. Devasena (2024) used to say that "Educators don't need to worry about artificial intelligence taking over their jobs. While AI is becoming a valuable tool for educational professionals, there are many ways computers just can't replace the human touch in the classroom."

Given these contextual challenges, the application of AI in language education at HUFLIT is not only timely but essential. By encouraging students to use AI tools for creative, task-based assignments—such as writing business role-play scripts, solving customer service problems, or producing promotional materials—educators can foster more meaningful and interactive learning experiences. In doing so, AI serves as both a cognitive assistant and a motivational force, empowering students to take ownership of their learning while adapting to the demands of a compressed academic schedule.

Based on these goals, the following research questions are posed:

1. *To what extent can artificial intelligence support lecturers and students in the Business English major?*
2. *How useful and effective is the application of artificial intelligence in teaching and learning the Customer Service course?*

2. Liteature review

2.1. The Role of AI in Modern Language Education

The advancement of human intelligence is artificial intelligence. One technology with significantly more education than it currently has is artificial intelligence. The most straightforward way to describe artificial intelligence is as theprocess by which computers mimic human intelligence (AI). Every facet of public life is being increasingly impacted by AI. Both the engine and the foundation of social progress are education (Devasena, 2024). In fact, AI appears in all aspects of life, for instance, education, industry, arts, music, films, engineering, medication, etc.

In language education, AI enables adaptive learning by tailoring content to individual proficiency levels, interests, and learning preferences. The application of AI into teaching and learning English is really practical and updated. There are so many AI tools to support teachers and students in teaching and learning process, such as, Grammarly for grammar feedback, ELSA Speak for pronunciation, Magic School for test composing, ChatGPT for scripts writing, etc. These applications encourage student autonomy and provide opportunities to practice English language skills asynchronously. With the rise of AI use in education, it is important for educators to understand how AI can be used to support the teaching and learning of English to those whose first language is not English. Therefore, a review of extant studies is needed to support the academic and practitioner community in understanding how AI is supporting English language educators and pupils (Crompton et al., 2024). Devasena (2024) mentioned in

his study that the methods and algorithms used in AI-powered tools for language learning vary depending on the specific tool. However, some common methods include natural language processing, machine learning, and deep learning.

In conclusion, if teachers and students do not know the ways to use the advantages of AI, their teaching and learning process is not so smooth and effective as the one of those using it. Consequently, artificial intelligence can effectively support classroom instruction and the development of English communication skills. Therefore, the development of artificial intelligence is not only a significant illustration of how science and technology can advance social change but also a useful tool for teaching and English (Devasena, 2024).

2.2. Strengths and weaknesses of AI in English for Specific Purpose (ESP) Instruction

2.2.1. Strengths of AI

In the era of 5.0, AI plays a vital role in English Language Teaching, especially in the domain of English for Specific Purposes (ESP), such as Customer Service course. Interactive English learning is made possible by artificial intelligence. English learning becomes more stereoscopic and visual through the connection and logical analysis of information such as visuals, music, and text in intelligent systems. Devasena indicated that students interact with AI through a manmachine interface, which not only makes the language environment more genuine but also corrects conversation mistakes in real time, allowing students to learn English in a more efficient manner (2024).

AI tools support these needs through personalized and context-relevant learning. ChatGPT, Gemini, for instance, enable learners to simulate dialogues between staff and customers, staff and managers or business partners, then generate the suitable solutions for each problem in customer care field. AI-generated content like articles, videos, and quizzes adapts to students' interests, lightening teachers' workloads, allowing for personalized support. AI technology revolutionizes English teaching, offering tailored, engaging, and effective learning experiences, adaptable to each student's preferences and needs (Devasena, 2024) . In general, AI-powered tools can be a valuable addition to the teaching toolkit, but they should not be seen as a replacement for human instructors. AI tools can be used to personalize the learning experience, provide timely feedback, and reach a large number of students. However, Shahidi (2023) said that AI tools are not able to provide the same level of in-depth instruction and engagement as human instructors.

In summary, AI is transforming the teaching and learning of Business English, especially in specialized courses like Customer Service. Though issues related to teacher readiness, ethical considerations, and learner dependence persist, the pedagogical benefits of AI—greater engagement, tailored feedback, and real-world skill development—are substantial. Fitria mentioned in his article that "To realize AI's full potential, sustained investment in teacher training, infrastructure, and ethical policy-making will be essential. English education need not be replaced by the Fourth Revolution. Instead of that the development of an English class model using Artificial Intelligence should work in collaboration with the English teaching and learning process. Language literacy and digital literacy are a neat combination to improve global competence" (2021). In the courses like Customer Service in which students must play the roles of service staff, sales manager, business partners, and customers AI tools are really useful because they play role as a peer or assessor. AI can accurately transcribe and assess students' spoken language. Rukiati et al. (2023) mentioned that by comparing their pronunciation, intonation, and fluency to native speakers, AI can provide instant feedback and

suggestions for improvement. Moreover, as virtual language tutors, AI can take part in interactive talks with students.

2.2.2. Weaknesses of AI

However, AI still has some backdraws if students depend on it so much. While AI can significantly enhance the process of second language acquisition, it is essential to note that it should complement, not replace, human instructors and real-life language practice. Songsiengchai et al. showed that AI can provide valuable support and resources, but meaningful communication and cultural understanding often require human interaction. The correlation between AI and SLA is evolving, with technology playing an increasingly prominent role in language education (2023). According to Shimbergenova (2026), when evaluated through the lens of communicative language teaching, the didactic limitations of AI tools become more evident. Communicative competence encompasses not only grammatical accuracy but also pragmatic appropriateness, discourse management, and sociolinguistic awareness AI tools often prioritize form focused instruction and struggle to address pragmatic competence, discourse coherence, and sociocultural nuances of language use. Moreover, overreliance on automated feedback may reduce learners' critical reflection skills if not mediated by instructors. Li and Meng (2021) indicated that current AI systems, despite advances in natural language processing, remain limited in their ability to engage learners in authentic interaction characterized by negotiation of meaning, turn-taking, and contextual interpretation. Empirical studies indicate that AI-mediated dialogues often rely on scripted or probabilistic responses, which may fail to reflect the complexity and unpredictability of real-life communication. Overemphasis on AI-driven practice risks narrowing language learning to decontextualized drills, thereby marginalizing communicative and intercultural dimensions of language use. Research in applied linguistics consistently demonstrates that meaningful interaction is essential for developing fluency and pragmatic competence. As a result, AI tools should be conceptualized as complementary resources rather than substitutes for communicative classroom practices (Shimbergenova, 2026). One another limitation is the AI reliance of students. Research highlights the risk of learner dependency on automated feedback. While immediacy of feedback is beneficial, excessive reliance on AI-generated corrections may reduce learners' capacity for self-monitoring and metalinguistic reflection. Hyland showed that from a didactic perspective, this necessitates balanced instructional design in which AI feedback is supplemented by reflective activities, peer interaction, and teacher-led discussion. Such integration ensures that learners remain cognitively engaged rather than passively responsive to automated prompts (2019). Another weakness comes from the educators. According to Holmes (2019), research indicated that many educators lack sufficient training to critically evaluate AI tools, interpret their outputs, or recognize their limitations. Without such competence, teachers may inadvertently accept automated feedback as authoritative, despite its potential inaccuracies. Didactic planning must include professional development initiatives that equip teachers with the skills to use AI responsibly, ethically, and pedagogically. Studies emphasize that AI tools yield optimal outcomes when teachers actively mediate their use by selecting appropriate tasks, interpreting automated feedback, and linking digital activities to broader learning objectives. Teachers are uniquely positioned to contextualize linguistic input, address learner affective needs, and promote higher-order thinking skills that AI systems cannot adequately support. Without such pedagogical intervention, AI applications may encourage surface-level learning focused on error correction rather than conceptual understanding (Shimbergenova, 2026).

In general, AI tools have both potisitive and negative impacts on teaching and learning English. Their effectiveness depends on pedagogical alignment, ethical governance, teacher mediation, and contextual appropriateness.

3. Methodology

This study adopted the action research design, which is well-suited for educational settings where practitioners aim to improve teaching and learning practices through reflective cycles of planning, action, observation, and evaluation. The research focuses on integrating artificial intelligence (AI) tools into Business English teaching and learning, specifically in the Customer Service course at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT).

For the lecturer, the intervention involved the application of AI tools such as Magic School, ChatGPT, and Gemini in lesson planning, student assessment, and class activities. For the students, these tools were used to support creativity, problem-solving, and communication skills in line with the learning objectives of Business English.

Participants in the study consisted of 420 third-year students majoring in Business English, enrolled in six different Customer Service classes taught by the researcher herself. These students were selected as at an advanced level in their major, with sufficient foundational knowledge to engage meaningfully with AI-supported learning activities.

Data Collection Methods included the following qualitative and quantitative approaches:

- Observation: The researcher conducted structured observations during classroom sessions, focusing on the interaction between students and AI tools, as well as the changes in engagement and learning outcomes. Students' reactions, attitudes and progress were scored each session by the researcher, using the classroom observation checklist during 12 weeks. *(appendix A)*
- Interviews: Semi-structured interviews were held with ten randomly selected students in the researcher's classes. The four interview questions explored the usability, effectiveness, and perceived impact of AI on teaching and learning activities. The answers of students were recorded by the researcher with a mobile phone. *(appendix B)*
- Survey: A Google Form survey was distributed to all 420 students at the end of the semester by sending a suvey link via Zalo groups of six classes taught by the researcher. The survey consisted of five questions and collected insights into their experiences using AI tools for Business English learning, highlighting perceived advantages, limitations, and areas for improvement. *(appendix C)*

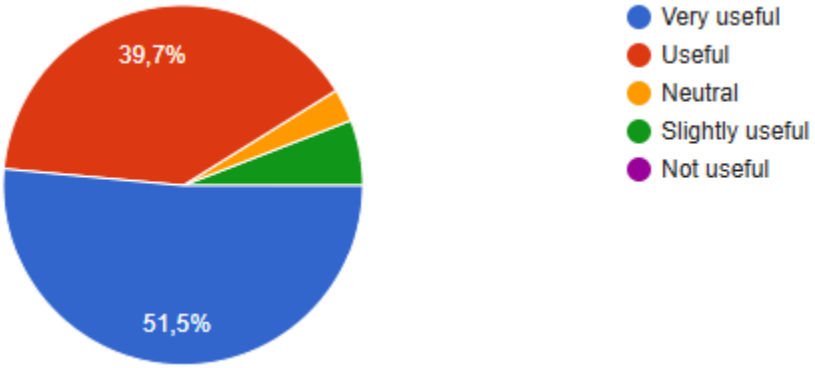
All collected data were analyzed thematically to identify recurring patterns and emerging insights. This process allowed the researcher to draw practical conclusions about the extent to which AI can enhance both teaching quality and student engagement in Business English courses.

4. Results

4.1. Findings From The Observation

Overall, the observation data collected from 12 weeks show that the integration of AI into Customer Service course had some notable outcomes. During 12 weeks, students demonstrated their increased engagement, communicative confidence, and interactions with their classmates. In role-play activities, students used AI to generate realistic conversations to

apply the useful languages in the textbook. In problem-solving situations, AI tools were used to simulate customer questions and generate suitable answers. Basing on the scripts written by AI tools, students adjusted into the conversation suitable with the scenarios and then practiced in class. In short, the observation data reveal that AI fosters a dynamic and efficient learning environment for those possessing low competence of language.

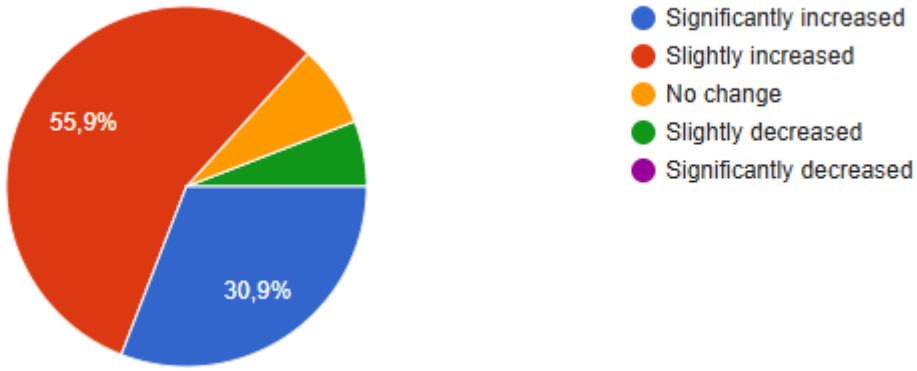


4.2. Findings from the interviews

The qualitative data of the semi-structured interviews including the four open questions indicated that the participants felt happy and satisfied with the integration of AI into teaching and learning Business English. The ten students said that their English speaking skills were improved significantly through some activities, for example, role-plays, problem-solving situations, and group presentations. Furthermore, participants noted that some AI tools lacked contextual sensitivity in business-specific situations. To improve the integration of AI in Business English learning, students suggested more teacher-guided use of AI, integration of AI tools tailored specifically to business contexts, and training on how to critically evaluate AI-generated content. In general, the findings suggest that while AI presents meaningful benefits in Business English education, careful instructional design and digital literacy support are essential to maximize its effectiveness and address potential drawbacks.

4.3. Findings from the survey

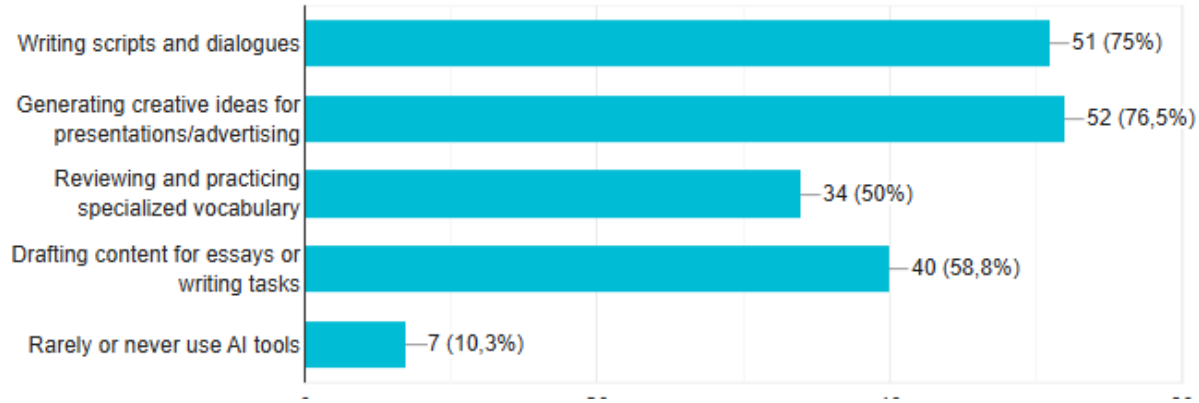
Figure 1



The usefulness of AI tools in Business English learning

The data presented in the figure indicate a predominantly positive perception of AI tools in Business English learning, with 51.5% of respondents rating them as very useful and another 39.7% considering them useful showing that over 90% acknowledge the supportive role of platforms like ChatGPT, Magic School, and Gemini. In contrast, only a small proportion of learners found them slightly useful or neutral, and notably, none deemed them not useful. The absence of negative evaluations further suggests smooth user experience with minimal technological or cognitive barriers. In general, the results highlight the pedagogical potential of AI tools not just as supplementary aids but as integral elements of Business English education, calling for their strategic integration into curricula to enhance engagement, language proficiency, and digital readiness among learners (see Figure 1).

Figure 2

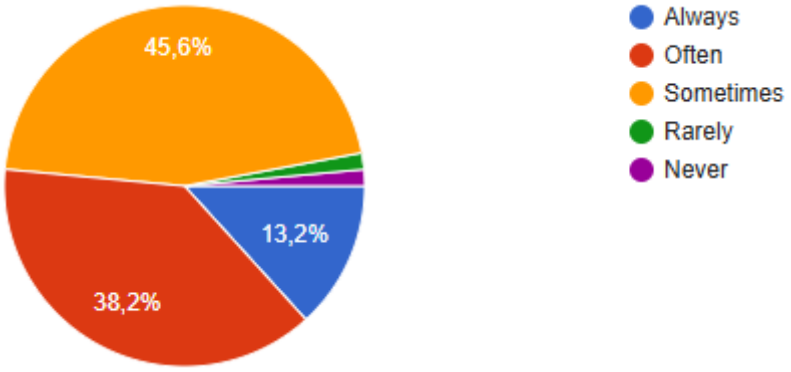


Students' engagement and motivation changes when using AI tools in learning

The results from the survey question "How has your engagement and motivation changed when using AI tools in your learning?" reveal a predominantly positive impact of AI on student motivation. According to the data, 55.9% of respondents indicated a slight increase, while 30.9% reported a significant increase in engagement and motivation when utilizing AI tools. This suggests that a combined 86.8% experienced some form of positive change, highlighting the potential of AI to enhance the learning experience. In contrast, only a small proportion of participants reported either no change (approximately 7%) or a slight decrease (approximately 6%), and notably, none reported a significant decrease. These findings imply that AI tools are generally well-received and can serve as effective motivators in educational contexts, particularly when integrated thoughtfully into learning environments. The minimal negative responses also suggest that concerns about reduced engagement may be less prevalent than anticipated. These results underscore the importance of incorporating AI-enhanced strategies in teaching to support and sustain learner motivation in evolving educational landscapes (see Figure 2).

Figure 3

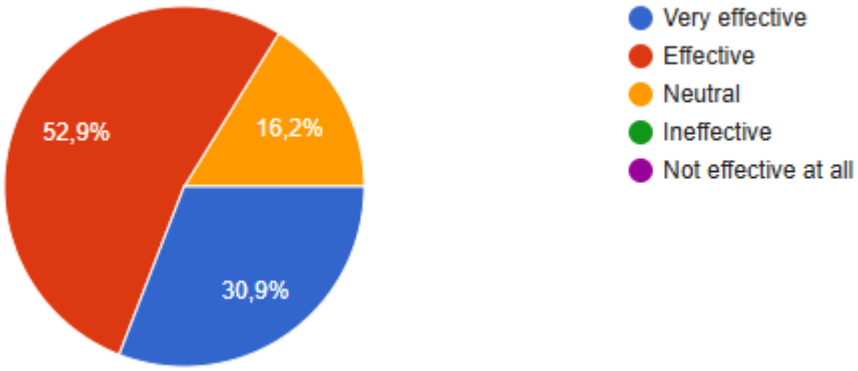
Types of learning activities students use AI for learning



The analysis of the survey results reveals that learners most frequently use AI tools for generating creative ideas for presentations or advertising (76.5%) and writing scripts and dialogues (75%), indicating a strong preference for leveraging AI in creative and communicative tasks. Moderate usage is seen in drafting content for essays or writing tasks (58.8%) and reviewing specialized vocabulary (50%), suggesting AI's role in supporting structured academic and lexical development. Only 10.3% of respondents reported rarely or

never using AI tools, reflecting a widespread integration of AI in language learning practices. These findings imply that AI is increasingly viewed as a valuable support tool in Business English learning, particularly for enhancing creativity, fluency, and domain-specific writing, and highlight the need for educators to incorporate AI meaningfully into instruction while fostering digital literacy and critical engagement with AI-generated content (see Figure 3).

Figure 4



Students rely on AI tools when completing assignments or preparing lessons

The pie chart illustrates the responses to the question, “Do you feel that you rely too much on AI tools when completing assignments or preparing lessons?” The majority of participants selected "Sometimes" (45.6%) and "Often" (38.2%), indicating that a significant portion of respondents perceive a moderate to high level of reliance on AI tools. A smaller proportion chose "Always" (13.2%), while very few reported "Rarely" or "Never," suggesting minimal usage. These findings imply that while AI tools are widely integrated into academic and instructional preparation processes, users are aware of their growing dependence. This suggests a need for further guidance on balanced usage to ensure that AI serves as a support tool rather than a replacement for critical thinking and pedagogical autonomy (see Figure 4).

Figure 5

The overall effectiveness of integrating AI into the Customer Service course

The pie chart presents respondents’ evaluations of the overall effectiveness of integrating AI into the Customer Service course. A majority of participants rated the integration as either "Effective" (52.9%) or "Very effective" (30.9%), suggesting a predominantly positive perception of AI's role in enhancing the course. Meanwhile, 16.2% of respondents expressed a neutral stance, and notably, no participants rated AI as "Ineffective" or "Not effective at all."

These findings imply that the implementation of AI tools in the Customer Service course has been largely well-received, indicating its potential to improve instructional quality, learner engagement, and practical skill development. The absence of negative responses further underscores a strong consensus among learners regarding the benefits of AI integration. Therefore, integrating AI into such vocationally oriented subjects appears to be a promising pedagogical strategy (see Figure 5).

5. Discussion

The integration of Artificial Intelligence (AI) into the Customer Service course at HUFLIT has significantly enriched Business English instruction by fostering student-centered and task-based learning. Platforms such as ChatGPT, ELSA, Magic School, and Gemini facilitated meaningful learner participation in communicative tasks, including role-plays, problem-solving, and script writing. These activities promoted both instructional effectiveness and learner motivation.

In response to research question 1, *To what extent can artificial intelligence support lecturers and students in the Business English major?*, findings indicate that AI can effectively support both lecturers and students by enhancing instructional customization and promoting more autonomous, motivated learning. Survey responses also reflected a degree of concern about potential over-reliance on AI. This underscores the importance of balance: AI should complement, not substitute, traditional instruction. Assessments must be designed to encourage original thought, iterative feedback, and collaborative work. Therefore, teachers must guide their students in adapting AI generated content to appropriate communicative contexts, avoid copy-paste methods.

Regarding research question 2, *How useful and effective is the application of artificial intelligence in teaching and learning the Customer Service course?* the majority of participants found AI both useful and effective for learning Customer Service English, confirming its practical value in ESP education. It demonstrated that with the Fourth Industrial Revolution where technology is very much integrated in teaching and learning, AI is the technology that every educator needs to be exposed to. AI is paramount in the language teaching and learning due to its various benefits (Ali, 2020). The findings will be of interest to educators who intend to integrate AI in their classrooms.

In summary, AI integration in HUFLIT's Business English curriculum has yielded substantial pedagogical gains, including heightened engagement, improved performance, and greater learner independence. However, these outcomes are best achieved when AI is deployed thoughtfully and ethically, under the guidance of skilled educators.

6. Conclusion

This study explores the integration of artificial intelligence in the teaching and learning of Business English at HUFLIT, with a focus on the Customer Service course. Drawing on data from classroom observations, student interviews, and surveys, the research highlights the substantial benefits AI offers in enhancing language instruction, learner engagement, and overall course effectiveness. AI tools such as ChatGPT, ELSA, Magic School, and Gemini were shown to support interactive, student-centered learning experiences by offering real-time feedback, language enhancement, and personalized support. Majority of students showed their motivation and communicative confidence when using AI to do activities such as role-plays, problem-solving scenarios, and group presentations. Moreover, teachers benefited a lot from AI integration through improved classroom management.

However, the research also revealed some concerns about over-reliance and occasional inaccuracies while majority of students appreciated the support AI provided. Therefore, both teachers and students have to combine the traditional pedagogical practices and the advantages of AI so that both can achieve the targets efficiently. Schools must provide students with digital literacy workshops, teachers must give clearer instructions on AI usage to their students before applying it into their teaching and learning at school to have the best results.

In a nutshell, the application of AI in teaching and learning Business English at HUFLIT has indicated to be effective and useful, especially for Customer Service course. When AI continues to develop, teachers and students must remain adaptive and intentional in its usage, making sure that technology serves to empower both teachers and students rather than diminish the autonomy and creation of the learners. Last but not least, future research needs to be done in this field to further explore long-term effects of AI application across different Business English courses at HUFLIT, for instance, Office Communications, English for Business, Business Communications, Negotiation Skills, English for Advertising and Marketing, Selling Skills, etc. and investigate the development of tailored AI tools for professional language education.

Nguyen Thi Bach Yen is a Doctor of Education (EdD) and a Master of TESOL. She is currently working as a lecturer of English at Faculty of Foreign Languages (FFL), HUFLIT, Vietnam. She likes working in a professional and creative working environment, especially with students who always have new ideas and innovations. With 24 years of teaching, she has been devoting a lot to research.

Appendices

Appendix A: Observation checklist

Observation Criteria	High	Moderate	Low	Notes/Examples
1. Students actively participate in AI-facilitated activities.	☐	☐	☐	
2. Students demonstrate interest/motivation when using AI tools.	☐	☐	☐	
3. Students collaborate with peers during AI-based tasks.	☐	☐	☐	
4. Students ask questions or seek clarification about AI outputs.	☐	☐	☐	
5. Students exhibit improvement or fluency through AI engagement.	☐	☐	☐	
Observation Criteria	**Yes**	**No**	**Partially**	**Notes/Examples**
6. Students use ChatGPT for language practice (e.g., generating responses, role-plays).	☐	☐	☐	
7. Students use Grammarly for writing correction and revision.	☐	☐	☐	
8. Students use ELSA Speak or similar apps for pronunciation practice.	☐	☐	☐	
9. Students engage in negotiation simulations with AI bots.	☐	☐	☐	
10. Students use AI tools independently with minimal instructor support.	☐	☐	☐	
11. Students reflect on AI feedback (e.g., revise based on AI suggestions).	☐	☐	☐	

Aspect	Rating (1–5)	Comments
Integration of AI into the lesson	☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5	
Student engagement with AI tools	☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5	
Effectiveness of AI in enhancing language learning	☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5	

Observation Criteria	High	Moderate	Low	Notes/Examples
Quality of instruction/facilitation	☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5			

Appendix B: Interview Questionnaire

Student Interview Questions: AI-Enhanced English Learning

1. How do you usually use AI tools (e.g., ChatGPT, Grammarly, ELSA Speak) when learning Business English?
2. What do you think are the most helpful features or benefits of using AI tools in your Business English learning process?
3. Have you faced any challenges or limitations when using AI tools to learn English? Can you give an example?
4. Do you think using AI tools has improved your English skills (e.g., writing, speaking, vocabulary)? Why or why not?

Appendix C: Survey Questionnaire

SURVEY QUESTIONNAIRE

Title: Application of AI in Teaching and Learning Business English at HUFLIT: strengths, weaknesses, and solutions

Target Group: Third-year Business English majors – Customer Service course

Purpose: To gather students' feedback on the strengths and weaknesses of using AI tools in learning Business English to have suitable solutions

Question 1: How useful do you find AI tools (e.g., ChatGPT, Magic School, Gemini) in supporting your learning in Business English?

☐ Very useful

☐ Useful

☐ Neutral

☐ Slightly useful

☐ Not useful

Question 2: How has your engagement and motivation changed when using AI tools in your learning?

☐ Significantly increased

☐ Slightly increased

☐ No change

☐ Slightly decreased

☐ Significantly decreased

Question 3: What types of learning activities do you most often use AI tools for?

☐ Writing scripts and dialogues

☐ Generating creative ideas for presentations/advertising

☐ Reviewing and practicing specialized vocabulary

☐ Drafting content for essays or writing tasks

☐ Rarely or never use AI tools

Question 4: Do you feel that you rely too much on AI tools when completing assignments or preparing lessons?

☐ Always

☐ Often

☐ Sometimes

☐ Rarely

☐ Never

Question 5: How would you evaluate the overall effectiveness of integrating AI into the Negotiation Skills course?

☐ Very effective

☐ Effective

☐ Neutral

☐ Ineffective

☐ Not effective at all

Thank you for your answers. We will keep them in privacy.

#45 TQM-oriented Service-Learning for EFL-ESL Transition: Social Responsibility at Pham Van Dong University

Võ Duy Quân[1]

Abstract

This study evaluates the efficacy of integrating Total Quality Management (TQM) into Service-Learning (SL) projects to fulfill University Social Responsibility (USR) and facilitate the transition from English as a Foreign Language (EFL) to a simulated English as a Second Language (ESL) environment. In provincial higher education institutions, executing USR is frequently constrained by limited resources, while learners lack authentic language practice environments.

An empirical study is designed at Pham Van Dong University (PDU), involving the entire cohort of third- and fourth-year pre-service English teachers. To optimize resource allocation, the research applies the TQM's PDCA (Plan-Do-Check-Act) cycle and internal quality control criteria to design, operate, and evaluate community-based teaching projects. Data are anticipated to be collected utilizing teaching portfolios, pre- and post-intervention professional agency scales, and quantitative local community social impact metrics.Data analysis is expected to demonstrate a statistically significant increase in pre-service teachers' professional agency post-intervention. Pedagogically, the TQM process is projected to standardize instruction, mitigate deployment risks, and successfully establish a sustainable micro-ESL space.

The findings will provide an empirical foundation for provincial higher education institutions to synchronize USR objectives with language transition policies through rigorous quality management.

Keywords: University social responsibility, EFL-ESL transition, service-learning, total quality management, pre-service teachers.

1. INTRODUCTION

Universities under the jurisdiction of provincial People's Committees have the primary missions of training local human resources, transferring knowledge, and directly addressing local socio-economic issues. Nevertheless, the execution of USR at these institutions faces significant barriers due to a deficiency in fundamental resources. The financial resources of these institutions rely predominantly on provincial budgets and tuition fee revenues. Due to local budgetary constraints, allocated funding is typically prioritized for recurrent operational expenditures. Concurrently, inadequate infrastructure and difficulties in attracting and developing highly qualified faculty members diminish the comprehensive operational efficiency of these institutions.

Consequently, due to resource constraints, provincial universities must often concentrate on pedagogical responsibilities, resulting in insufficient emphasis on the functions of scientific research and community service. As a result, USR has not been systematically integrated into their overall governance strategies. Community activities are predominantly

[1]*Center for Student Support, Corporate Relations and Entrepreneurship, Pham Van Dong University; Email: vdquan@pdu.edu.vn*

campaign-driven and consist of short-term voluntary initiatives conducted by mass organizations. The absence of dedicated personnel and specific funding mechanisms hinders these institutions from implementing academically rigorous and long-term cohesive SL projects. This situation necessitates the restructuring of governance models and the establishment of multi-stakeholder collaboration mechanisms to maintain sustainable USR execution capabilities.

Within the scope of foreign language education, a prominent issue currently is the lack of authentic communicative environments necessary to facilitate the transition of EFL to ESL. At provincial universities, instructional activities predominantly occur within traditional classrooms, focusing on grammar and foundational skills, while lacking contexts for social interaction. This deficiency restricts learners' communicative reflexes and their ability to use the language naturally.

To address this issue, SL is implemented as a central pedagogical approach. Through community projects, such as organizing pre-service teachers to directly teach English to disadvantaged children, learners are transitioned from the classroom environment into practical communicative contexts. Participation in these projects enables pre-service teachers to directly apply their specialized knowledge while simultaneously developing social responsibility, thereby effectively facilitating the transition from EFL to ESL.

Based on this practical rationale, the present study is conducted to evaluate the efficacy of integrating the TQM model into SL projects to fulfill USR and support language practice environments. Rather than pursuing dispersed objectives, the research focuses on two core objectives: (1) Evaluating the operational effectiveness of the PDCA cycle in standardizing pedagogical procedures within SL projects, and (2) Measuring the project's impact on the development of pre-service teachers' professional agency. To achieve these objectives, the study addresses two core research questions:

1. How does the TQM's PDCA cycle assist in standardizing community teaching activities and mitigating risks?
2. How does participation in a TQM-oriented project impact the professional agency of pre-service teachers?

2. LITERATURE REVIEW

2.1. University Social Responsibility and Service-Learning

USR is a foundational governance strategy that directs higher education institutions to create a positive impact on society. This strategy requires institutions to integrate ethical standards and sustainable development goals into two core missions: training and research (Du, 2025; Phan, 2022). To translate the USR strategy into educational practice, SL is utilized as a central pedagogical mechanism. This method establishes a direct linkage between the educational institution's community service mission and the students' practical learning process (Coelho & Menezes, 2021; Lê, 2024).

This linkage operates based on translating governance commitments into practical actions. USR constructs the macro-policy framework, whereas SL serves as the direct implementation tool. The core distinction between SL and volunteer activities is the requirement for students to apply their specialized knowledge to solve local problems, subsequently undertaking steps of academic reflection. This procedure ensures that the educational institution simultaneously achieves its learning outcomes and addresses the practical needs of the community (Nguyễn, 2024; Phạm, 2025; Trần, 2020), while concurrently

developing professional competencies and civic consciousness. The objective of USR is to cultivate a socially responsible workforce. Participation in SL places students in diverse and complex social contexts. The process of resolving practical problems assists learners in cultivating critical thinking, consolidating their professional foundations, and enhancing their awareness of vulnerable groups. Consequently, learners clearly delineate their personal responsibilities towards collective development (Nguyễn & Trần, 2023; Pham & Le, 2025) and establish sustainable partnerships. Through SL, the institution transitions from a unilateral knowledge transfer modality to a bilateral collaborative mechanism with the locality. The educational institution, students, and community partners mutually share resources to address challenges. This interactive mechanism provides empirical evidence affirming the university's capacity for governance and the execution of its social responsibility (Dư, 2025; Ngô, 2023).

2.2. Total Quality Management and the PDCA Cycle in Teacher Education

TQM is a management approach directed towards the continuous improvement of operational processes to meet the standards of the educational system (Bùi & Nguyễn, 2020). The core control instrument of TQM is the Deming cycle, which encompasses four phases: Plan, Do, Check, and Act.

The application of PDCA in teacher education requires educational institutions to transition from management by objectives to process-based control (Nguyễn, 2014). During the Planning phase, the institution determines learning outcomes and program structures based on data from sectoral needs analysis. The Execution (Do) phase involves the organization of instruction, professional training, and the allocation of educational resources. The Checking phase focuses on measuring the actual competencies of learners, as well as collecting feedback data from employers and practicum-hosting institutions. In the Improvement (Act) phase, the institution utilizes the analyzed data to adjust instructional content and training methodologies to prevent procedural discrepancies. The PDCA cycle establishes a self-regulatory mechanism, ensuring that the competencies of pre-service teachers consistently align with practical requirements (Nguyễn, 2023).

2.3. Establishing a simulated ESL environment (micro-ESL space) through Service-Learning

The English language education model in Vietnamese higher education currently operates primarily with an EFL orientation. Students acquire the language within the classroom environment, focusing on grammatical structures rather than utilizing the language as a tool for social communication. To address this issue, SL projects are implemented to establish simulated ESL environments.

According to language socialization theory, language acquisition achieves high efficacy when learners interact within practical contexts. SL provides a natural communicative environment, requiring learners to use authentic language to convey information and execute community-based tasks (Truong et al., 2020). When English-major students directly teach English to children, they are compelled to self-regulate their skills and control their vocabulary to ensure instructional effectiveness. The subsequent process of academic reflection assists students in systematizing their knowledge, rectifying errors, and mitigating psychological anxiety. This constitutes the empirical foundation for students to complete the transition from passive EFL learners to independent ESL users (Bùi, 2023; Tuan & Bao, 2021).

2.4. Professional agency of pre-service teachers in practical environments

Professional agency is the capacity to proactively regulate pedagogical behavior, make independent decisions, and resolve problems within practical contexts (Tran, 2019). For pre-service teachers, this capacity is cultivated only when learners are granted the autonomy to design instructional methods, rather than adhering to pre-existing procedural templates.

The SL environment provides the practical context for pre-service teachers to develop this capacity. Unlike traditional practicums characterized by stringent supervision from mentor teachers, participating in community projects requires pre-service teachers to independently organize educational activities for specific target demographics. Pre-service teachers must directly analyze situations, select pedagogical approaches, and resolve emerging risks (Tuan & Bao, 2021). Through direct practice combined with maintaining reflective journals, pre-service teachers evaluate the consequences of their professional decisions. This process shifts the status of pre-service teachers from passive observers to proactive controllers of pedagogical activities, effectively applying academic theories to authentic educational environments.

3. RESEARCH METHODOLOGY

3.1. Research design and participants

The study adopts a mixed-methods experimental design, conducted at PDU to verify the efficacy of integrating TQM into SL projects.

The research participants comprise third- and fourth-year pre-service English teachers. The quantitative survey sample size is determined to be N = 80 pre-service teachers to ensure reliability and statistical validity.

3.2. Intervention procedure of the PDCA cycle

The experimental intervention is operationalized through the integration of the TQM framework and the institution's internal quality assurance (IQA) criteria, strictly adhering to the PDCA cycle:

Plan: Optimizing the allocation of resources (human, financial, and instructional materials) based on the TQM framework to design projects that closely align with program learning outcomes and local needs.

Do: Organizing pre-service teachers to directly implement practical foreign language teaching activities in community settings.

Check: Utilizing IQA criteria to monitor progress, measure the quality of teaching sessions, and collect feedback from local partners.

Act: Utilizing evaluation data to adjust operational procedures and update pedagogical support methods to standardize subsequent cycles.

3.3. Data collection instruments and methods

Research data are collected concurrently through both quantitative and qualitative channels:

Quantitative instruments: Utilizing the Professional Agency Scale (adapted from the theoretical framework of Tran, 2019), which comprises 18 items measured on a 5-point Likert scale. The survey is administered before and after the intervention (pre-test & post-test) to the 80 pre-service teachers to measure the degree of change. The items are rigorously tested for internal consistency reliability using Cronbach's α coefficient. Concurrently, quantitative social impact metrics (total service hours, number of beneficiaries) are collected to measure the efficacy of USR execution.

Qualitative instruments: Examining Teaching portfolios, including lesson plans and specifically the weekly reflective journals of the 80 pre-service teachers, to evaluate the development in pedagogical thinking and to elucidate the risk management mechanisms underlying the statistical data.

4. RESULTS

4.1. Statistically significant increase in professional agency

To evaluate the impact of the TQM-oriented SL project on pre-service teachers, the study conducted a Paired-Samples T-test on the professional agency scale before and after the intervention. Data were collected from the entire cohort of 80 third- and fourth-year pre-service teachers. Prior to conducting the difference analysis, the data were tested for normal distribution using the Shapiro-Wilk test ($p > .05$), ensuring the fulfillment of conditions for parametric statistics**.**

Table 1. Paired-samples t-test results for pre- and post-intervention Professional Agency (N = 80)

Dimensions of Professional Agency	Phase	M	SD	t	df	p
Overall	Pre-test	3.15	0.62	-15.42	79	**< .001**
	Post-test	4.28	0.45			
1. Pedagogical Awareness	Pre-test	3.20	0.65	-10.85	79	< .001
	Post-test	4.15	0.50			
2. Classroom Management	Pre-test	2.95	0.70	-14.60	79	< .001
	Post-test	4.35	0.48			
3. Social Responsibility	Pre-test	3.30	0.58	-12.35	79	< .001
	Post-test	4.40	0.42			

The data analysis results (Table 1) indicate a statistically significant increase in the pre-service teachers' professional agency post-intervention. Specifically, the overall mean score increased substantially from $M = 3.15$ ($SD = 0.62$) in the pre-test to $M = 4.28$ ($SD = 0.45$) in the post-test ($t = -15.42$, $p < .001$). The most notable improvement was recorded in the Classroom Management dimension (increasing from 2.95 to 4.35), demonstrating that practical exposure robustly assisted pre-service teachers in developing their pedagogical operational and situational problem-solving skills.

4.2. Standardization of instruction and risk mitigation via PDCA

Alongside quantitative data, qualitative data extracted from the pre-service teachers' teaching portfolios clearly demonstrated the role of the PDCA cycle in standardizing instruction and mitigating deployment risks.

4.2.1. Plan and Do

The application of TQM's internal quality assurance IQA criteria right from the lesson planning stage established a robust pedagogical framework. Pre-service teachers were compelled to anticipate local resource constraints to design appropriate lessons. A fourth-year pre-service teacher (SV45) reflected in their journal: *"Initially, I intended to design the lesson based on situational videos and interactive screen-based games. However, upon cross-checking with the resource checklist of the 'Plan' step, I realized that the community cultural*

house was not equipped with a projector system and Internet connection (Wi-Fi). I promptly transitioned to designing large-format flashcards and organizing total physical response (TPR) activities during the 'Do' step. The lesson remained highly engaging; students were not distracted by devices and interacted more directly with the teacher."

4.2.2. Check and Act

The TQM cycle permits the immediate identification of risks rather than waiting until the end of the term. The continuous collection of feedback assists pre-service teachers in adjusting their pedagogical behavior. Another excerpt from a third-year pre-service teacher (SV12) emphasizes the effectiveness of pedagogical risk mitigation: *"After the second teaching session, the 'Check' step with the mentor indicated that I was speaking Vietnamese too much (accounting for 60% of the instructional time). In the following week (Act), I rigorously applied basic Classroom English techniques. Although the local students were initially somewhat unfamiliar, after just two sessions, they responded naturally to English commands."*

4.3. Establishment of micro-ESL space and USR metrics

The integration of TQM into the project not only optimized resource allocation but also successfully established a sustainable simulated ESL environment, directly fulfilling the USR objectives at a provincial higher education institution.

Table 2. *Quantitative local community social impact metrics (USR Metrics)*

USR Metrics	Empirical Data
Resource Allocation	The entire cohort of 80 third- and fourth-year pre-service teachers
Total hours establishing the ESL environment	3,200 hours (80 students x 40 field hours)
Number of direct beneficiaries	520 students/residents in disadvantaged communes
Target Language Use	Averaged 85% of the duration per instructional session
Sustainability Index	100% of community classes completed the committed scheduled duration

The quantitative social impact metrics (Table 2) demonstrate the robust execution of USR. Utilizing a core workforce of 80 pre-service teachers, the project provided 3,200 hours of free instruction, directly benefiting 520 local learners.

Notably, the authentic English utilization rate reaching 85% during the instructional sessions constitutes clear evidence of the successful establishment of a simulated ESL environment (micro-ESL space). Instead of acquiring English through textbooks within a traditional EFL model, local learners were immersed in a simulated ESL environment, where the language is utilized as a dynamic and continuous communicative tool. This affirms that, despite resource constraints, provincial higher education institutions can entirely synchronize their USR objectives with language status transition strategies through a rigorous TQM system.

5. DISCUSSION

This study has demonstrated the efficacy of integrating TQM into SL projects to address specific challenges at provincial higher education institutions. The findings from the empirical

data not only confirm the enhancement of pre-service teachers' competencies but also introduce novel approaches in university governance.

5.1. TQM and Resource Management

At provincial higher education institutions, the execution of USR is frequently hindered by limitations in financial, infrastructural, and human resources. The research results indicate that TQM, particularly the PDCA cycle, functions as a leveraging mechanism to optimize the allocation of these resources.

Instead of necessitating massive investments, the application of IQA criteria from the Planning phase compels the institution and pre-service teachers to accurately identify the existing conditions of the community (e.g., communal cultural spaces, village halls) to restructure them into learning spaces. During the Check and Act phases, the TQM procedure assists in the early detection of pedagogical bottlenecks and resource waste, thereby enabling flexible adjustments without incurring additional costs. In other words, TQM has shifted the governance paradigm from resource deficiency to the optimization of existing assets, transforming SL into a highly feasible and economically viable modality for USR execution.

5.2. USR and Language Transition Policy

One of the strategic contributions of this study is the successful establishment of sustainable simulated ESL environments (micro-ESL spaces). At the macro level, national and local language policies consistently aim to enhance the English proficiency of the general population; however, learners in provincial areas lack authentic language practice environments.

By integrating 80 pre-service teachers deeply into the community, the project created a simulated ESL environment, where English is utilized as a practical communicative tool rather than merely as a pure EFL subject in traditional classrooms. Rigorous quality management serves to integrate two major objectives: executing the institution's community service mission USR while simultaneously establishing an extensive language practice network, thereby directly contributing to the goal of transitioning the status of English locally. This provides a robust empirical foundation for provincial higher education institutions to synchronize their social responsibility objectives with language policies.

5.3. Developing Professional Identity

The statistically significant increase in the professional agency of pre-service teachers post-intervention constitutes crucial evidence for the efficacy of this pedagogical model. Upon participating in the TQM-oriented SL model, the roles of third- and fourth-year students underwent a qualitative shift.

In contrast to traditional practicums where students primarily assume the role of passive apprentices, directly designing, operating, and evaluating community teaching projects based on the PDCA framework requires them to continuously make pedagogical decisions and bear responsibility for output quality. The process of confronting and mitigating deployment risks in field environments has awakened a profound sense of social responsibility. From the position of education beneficiaries, they realize that their professional expertise can address educational inequality issues at the grassroots level. This shift in professional identity, transitioning from a mere language learner to an agent of social change, represents the highest core value that higher education provides to both learners and the community.

6. CONCLUSION AND IMPLICATIONS

6.1. Conclusion

This study has successfully achieved its objective of evaluating the efficacy of integrating TQM into SL projects at PDU. The empirical data affirm that TQM transcends the framework of a business theory to become a rigorous pedagogical management tool. Through strict adherence to the PDCA cycle, the research has successfully standardized instructional procedures, mitigated field deployment risks, and yielded a statistically significant increase in the professional agency of the pre-service teachers.

TQM serves as the pivotal mechanism assisting provincial universities in resolving the challenge of resource scarcity to synchronize two strategic objectives. These are the comprehensive execution of USR concurrently with the successful establishment of a sustainable simulated ESL environment (micro-ESL space), thereby creating momentum for transitioning the status of EFL to a simulated ESL environment for the community.

6.2. Policy Implications

Based on the aforementioned empirical findings, this study provides a data foundation and proposes the following policy implications for provincial higher education institutions:

(1) Restructuring community activities based on Quality Management

Provincial universities need to transition traditional volunteer activities into a SL model oriented by a quality management approach. The integration of IQA criteria into the project design, operation, and evaluation phases is mandatory to optimize resource allocation (human, financial, and instructional materials) and ensure sustainability.

(2) Synchronizing USR with language transition strategies

Local educational administrators should develop mechanisms to integrate social responsibility objectives into foreign language proficiency development schemes. Utilizing the cohort of pre-service teachers as the core workforce to establish authentic language practice environments at the grassroots level not only thoroughly resolves the learners' lack of authentic communicative spaces but also maximizes local budget savings.

(3) Integrating Service-Learning into the Teacher Education curriculum

To develop profound professional agency, it is necessary to formalize the TQM-oriented SL model into a compulsory practicum module or a learning outcome assessment standard for final-year pre-service teachers, rather than merely treating it as short-term extracurricular campaigns.

#46 Examining The Factors Affecting The Employment of ChatGPT in Translation Among English Majors at HUFLIT as Vietnamese Education Transitions From EFL To ESL Orientation

Huong Le[1]

Abstract

The proliferation of ChatGPT has facilitated the learning of translation subjects among language learners, and this is especially true when Vietnam aims to transition English from EFL to ESL. The omnipresence of the chatbot in translation courses proves its effectiveness in assisting learners to achieve their academic targets; nevertheless, the factors behind students' actual employment of the tool seem to have been inadequately explored. This paper aims to investigate the determinants of the employment of ChatGPT in translation among English-majored students. The study involved 138 students of English in their second and third years at Ho Chi Minh City University of Foreign Languages - Information Technology (HUFLIT) utilizing a mixed-methods approach. The findings suggest that intrinsic and extrinsic motivation as well as social influence stand out to be pivotal factors influencing the adoption of ChatGPT in translation assignments among the surveyed students, while the impacts of Perceived Usefulness and Perceived Ease Of Use on the actual use of the tool are negligible. The study also places an emphasis on the equipment of students with essential linguistic knowledge, post-editing competencies, and higher-order thinking skills to effectively utilize ChatGPT for translation subjects while simultaneously encouraging lecturers to make transformations or adaptations in translation pedagogy, drawing students' attention to meaning- and context-oriented translation, fostering interactivity, critical translation and comprehension skills, and ethical awareness of adopting ChatGPT in classroom activities to be aligned with the national orientation of making English become a second language rather than a foreign one.

Key words: factors, employment of ChatGPT, translation, ESL orientation

1. Introduction

The introduction of Artificial Intelligence (AI) tools in language education has made revolutionary changes to both conventional teaching and learning methods (Ghimire et al., 2024), with English being no exception. Teachers have adopted a mixed variety of AI tools to facilitate their teaching process and increase their teaching efficiency (Ghimire et al., 2024), ranging from lesson planning, grading tests, automating assessment (Aljabr & Al-Ahdal, 2024; Amin, 2023; Ferreiro-Santamaria, 2024; Jukiewicz & Wyrwa, 2026; Moqbel & Al-Kadi, 2023; Yavuz et al., 2025) to enhancing the quality of their teaching materials through the creation of stimulating learning activities and the transformation of dry, boring lessons into vivid, intriguing PowerPoint slides with more interactive and appealing content (Li et al., 2025). Meanwhile, learners of language have also taken full advantage of these tools to maximize their learning capacity, undertake self-study, or implement research on the language issues they wish to delve into (Ghimire et al., 2024).

[1] *M.A., Lecturer, Faculty of Foreign Languages, Ho Chi Minh City University of Foreign Languages – Information Technology (HUFLIT), Ho Chi Minh City, Vietnam; Email: huongltt@huflit.edu.vn*

Translation-related disciplines have also witnessed a dramatic rise in the use of AI tools. Such AI-assisted translation tools as Google Translate, ChatGPT, Gemini, and DeepSeek have played an increasingly important role in enabling learners to handle translation of texts with varying degrees of difficulty. Among these, ChatGPT stands out as a favorable assistant tool for offering immediate, customized feedback tailored to individual learners' demands (Abdallah et al., 2025; Amin, 2023; Ghimire et al., 2024; Pokrivcakova, 2019; Ren, 2025), providing a diversity of linguistic phrases and structures of different levels of complexity, as well as enhancing the precision and speed of translation process (Ren, 2025).

In Vietnam, the employment of ChatGPT in translation learning is increasingly popular, especially when the nation intends to institutionalize English into the education system as a second language across all educational settings by 2035 (Kiet, 2025). Kiet (2025) also adds that the project proposed by the Ministry of Education and Training (MoET) aims to use English as a means of knowledge transmission and day-to-day communication, and this policy shift is to help the country's future labor force successfully integrate into the increasingly competitive global market which is placing growing demands on employees' linguistic abilities. According to the MoET, the new orientation requires English learners to possess better communicative competence, a greater degree of learner autonomy, as well as enhanced lifelong learning capacity and cognitive abilities (Vietnam's smart shift in education, 2025). This also suggests significant implications for translation pedagogy where ChatGPT is mainly adopted out of convenience and personal favorability.

Numerous studies exploring the factors behind the adoption of ChatGPT in educational contexts in general (Al-kfairy, 2024; Alotaibi et al., 2025) and in language settings in particular (Almansour, 2024; Diep & Dang, 2025; Kartini et al., 2025; Qu & Wu, 2024; Ren, 2025) have been conducted since its emergence. However, these studies mainly focused on the indirect effects of such factors as Perceived Usefulness, Perceived Ease Of Use, Motivation, and Social Influence on the adoption of ChatGPT in translation through a mediator called behavioral intention. The direct impact of these factors on the actual employment of ChatGPT in translation in higher education settings has been under-researched. Therefore, this paper seeks to investigate the determinants behind English majors' actual employment of ChatGPT in assisting them in translation courses in a Vietnamese tertiary education institution, specifically in the ESL-transitioned context.

The objective of the study is to examine the factors influencing the employment of ChatGPT in translation among English majors at HUFLIT. The research paper attempts to find out the answers to the following questions:

1. What are the factors influencing English-majored students at HUFLIT to adopt ChatGPT in their translation courses?
2. What skills can be explicitly taught to English-majored students as ChatGPT is formally integrated into translation courses?
3. What kinds of pedagogical instructions or strategies could be incorporated into translation teaching when ChatGPT becomes a formal tool for teaching and learning English?

2. Literature Review

2.1. The use of AI in language education

2.1.1. The benefits of using AI in language education

Plenty of research studies investigating the application of Artificial Intelligence (AI) in language education have credited AI assistant tools for their capabilities of customization, content adaptation to well suit language learners' individual learning needs and the ability to provide detailed analysis of their spoken as well as written outputs and meticulous, instantaneous feedback to help improve their academic performance (Gutiérrez, 2023; Pokrivcakova, 2019; Semerikov et al., 2021; Tafazoli, 2024; Zhu & Wang, 2025). Additionally, AI-powered tools have been found to be able to produce conversations and pieces of writing that bear a great resemblance to those of humans in terms of language use and register (Aljabr & Al-Ahdal, 2024; Gutiérrez, 2023). Most notably, from the perspective of Gutiérrez (2023), AI tools can aid learners in the process of sharpening their linguistic skills owing to its offer of language practice opportunities, along with acting as a source of inspiration (Ali et al., 2023) and engagement enhancement (Abdallah et al., 2025; Ali et al., 2023), which could contribute to interest maintenance among learners. Ferreiro-Santamaria (2024) suggests another important positive effect arising from the adoption of AI in English classrooms, which is the increase in learner autonomy, a prerequisite assisting students in acquiring a language.

2.1.2. The drawbacks of using AI in language education

However, many studies have pointed out some of the limitations in the use of AI tools to facilitate learning process. The first concern involves the production of inaccurate information (Ferreiro-Santamaria, 2024; Gutiérrez, 2023; Vinola et al., 2025), which entails the issue of response reliability (Gutiérrez, 2023; Vinola et al., 2025), and the potential for biases and excessive reliance on content generated by AI (Abdallah et al., 2025; Ferreiro-Santamaria, 2024; Gutiérrez, 2023; Li et al., 2024). The application of AI-powered tools in language education has also been reported to be a major hindrance to the development of teachers' specialized knowledge (Li et al., 2024), the diminution in students' critical thinking (Abdallah et al., 2025; Ferreiro-Santamaria, 2024; Li et al., 2024; Vinola et al., 2025) and social skills due to the shortage of direct interactions, and the increased violation of academic integrity among learners of language (Abdallah et al., 2025; Ferreiro-Santamaria, 2024; Li et al., 2024).

2.2. The adoption of ChatGPT in translation

2.2.1. Translation

According to Ismail & Syahruzah (2017), translation involves the process of conveying meaning of written texts across languages, or more specifically, it is the conversion of meaning from the original language, or commonly known as the source language, into the target language. Sharing the same view; however, Fitria (2018) maintains that translation not only centers around a change in forms, but it also places an emphasis on meaning and style change through the employment of equivalents. A translation of high quality can be produced based on the degree of "accuracy, clarity, and naturalness" (Akil, 2011, p. 2). Among these, the precision of meaning is the most important element contributing to translation quality, which is not just confined to correct idea expression but embraces the transfer of meaning in a contextually and culturally appropriate manner.

2.2.2. The advantages of adopting ChatGPT in translation

On the one hand, the increasingly prevalent use of ChatGPT in translation can be attributed to its competence in generating translations of high degrees of accuracy, pertinence, authenticity, speed with no cost (Roza & Zulhirawati, 2023; Vinola et al., 2025). Time efficiency in proofreading has also been cited as a prominent benefit of using ChatGPT to translate various kinds of texts as students can take advantage of prompts to require ChatGPT to refine the original translations in a diversity of aspects (Vinola et al., 2025). In fact, just by

inputting a specific prompt demanding revision and edition of the translated texts, the tool is able to generate a more precise version of the original one just in less than a second, which helps to save learners a large amount of time on text refinement. Vinola et al. (2025), in their research, have pointed out ChatGPT's flexibility in translation as it can produce texts that are appropriate in terms of styles based on the prompt it receives. An additional strength of using ChatGPT in translation is its brilliant capabilities of structural conformity (Badah et al., 2026), which means the tool is competent in expressing ideas in grammatically correct structures with coherence and without meaning loss.

2.2.3. The disadvantages of adopting ChatGPT in translation

On the other hand, ChatGPT manifests some of its weaknesses, with the first being associated with its ability to translate idioms, cultural subtleties (Manapbayeva et al., 2024; Mohsan & Durr-e-Nayab, 2024; Rousan et al., 2025) and figurative texts as well (Manapbayeva et al., 2024). Because of its limitation in cultural backgrounds, ChatGPT cannot preserve the meaning of the source language when it is translated into the target language. When it comes to translating literary texts, a study implemented by Manapbayeva et al. (2024) reveals that ChatGPT faces a challenge in conveying nuances related to cultures and contexts since its large database tends to provide very general pieces of translation that can overlook cultural sensitivities. Manapbayeva et al. (2024) also raise concerns over the retention of "the stylistic and cultural integrity of the original text" (p. 527) and match these elements with the significance of contextual awareness in translation so as to maintain the purpose and tone of the writer. As for poems, the greatest obstacle to be surmounted by ChatGPT is how to preserve the style and "emotional integrity" (p. 531) conveyed in the original language (Manapbayeva et al., 2024). In their research conclusion, Manapbayeva et al. (2024) suggest the best possible approaches to improve ChatGPT's accuracy in literary translation are to integrate human expertise, feedback, and refinement for better interpretations of cultural and emotional layers existent in the texts. In a similar vein, a recent study undertaken by Albalawi & Abdul-Ghafour (2026) finds that ChatGPT's translations in euphemisms were inconsistently accurate in terms of context, culture, and meaning nuances, thereby resulting in a lack of depth in meaning and cultural inappropriateness. Badah et al. (2026) shares the same view with the previous researchers when pointing out that ChatGPT still struggles with the translation of culturally rich language despite its prominent competence in "structural coherence" (p. 5).

Students who employ ChatGPT as a translation tool also encounter a problem concerning overdependency and reduced translation skills (Vinola et al., 2025). Such skills as researching for suitable and relevant linguistic items and structures, textual analysis, and proofreading, along with the application of linguistic knowledge and cultural consciousness could be greatly undermined if students opt for this AI tool to help them handle translation assignments.

2.3. Theoretical Framework

2.3.1. Technology Acceptance Model (TAM) Theory

A theory of critical importance that serves as a theoretical basis for this study is the Technology Acceptance Model (TAM) theory proposed by Fred David in 1989. Sharp (2007) cited in his research that TAM theory is a model that lays the foundation for the examination of factors influencing users' acceptance of a particular technological tool. Among this model, two fundamental constructs, namely Perceived Usefulness (PU) and Perceived Ease Of Use (PEOU), make an impact on people's attitude towards the use of technology, which in turn influences their behavioral intention of its employment (Alotaibi et al., 2025; Hadalgekar &

Desai, 2025; Lai, 2017). Perceived Usefulness refers to the degree of effectiveness brought about by adopting a new technology on the betterment of an individual's work performance or the accomplishment of a desired result, while Perceived Ease Of Use is defined as the simplicity and user-friendliness of using the technology (Alotaibi et al., 2025; Hadalgekar & Desai, 2025; Harryanto et al., 2018; Lai, 2017; Sharp, 2007). According to Sharp (2007), the findings of the first two studies implemented by Fred Davis in 1989 suggested that Perceived Usefulness exerted a stronger effect on people's adoption intention of a technology compared to Perceived Ease Of Use, and Perceived Ease Of Use preceded Perceived Usefulness, whereas the following study concluded that attitude should be excluded from the model since it did not fully affect the two above-mentioned constructs.

2.3.2. Self-Determination Theory (SDT)

Motivation has been viewed as an element that is of immense importance to the acquisition of a language (Rubić & Matijević, 2019). In other words, success or failure in learning a language greatly depends on how motivated learners are; therefore, gaining an in-depth insight into how motivation impacts on individual learning may assist teachers in adjusting their methods to stimulate students' engagement and interest. Proposed by Deci and Ryan (1985), the Self-Determination Theory is known as a theory examining the relationship between people's motivation and their character traits (Jeno et al., 2017). In this model, students are active learners possessing three fundamental psychological needs, which are "autonomy, competence, and relatedness" (Deci and Ryan, 1985, p. 2, cited in Jeno et al., 2017). These psychological needs are inherent and central to the strengthening of motivation and the direction of people's feelings and behaviors (Rubić & Matijević, 2019). Deci and Ryan (1985, cited in Jeno et al., 2017) categorized motivation into intrinsic and extrinsic motivation, with the former being behavioral actions based on internal sense of delight and pleasure, while the latter indicates behaviors that are exhibited to gain specific outcomes. Annamalai et al. (2023) describe autonomy as the independence to take control of one's own actions or behaviors, defining relatedness as a feeling of connection with other people while referring to competence as the mastery of a task or a related skills set. They elaborate on the correlation between these demands and motivation development and suggest a possible transition from extrinsic to intrinsic motivation once students' psychological needs are satisfied. The Self-Determination Theory also underlines the promotion of a positive learning environment since this can greatly facilitate the nurture of students' psychological needs (Jeno et al., 2017) and highlights the need for instruction to help students regulate extrinsic motivation into internal one, which in turn arouses their genuine curiosity as well as interest and makes them consider learning a rewarding experience (Rubić & Matijević, 2019).

2.3.3. Unified Theory of Acceptance and Use of Technology (UTAUT)

Another theory that is also vital to the understanding of people's decision on adopting technology is the Unified Theory of Acceptance and Use of Technology (UTAUT) formulated by Venkatesh et al. (2003, cited in Venkatesh et al., 2016), which explains the four principal constructs behind individuals' acceptance and employment of a particular technology: Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions (Fatoni & Surani, 2022). Performance Expectancy (PE) is interpreted as individuals' belief of accomplishments in their career performance when putting a system into use, whereas Effort Expectancy (EE) refers to the level of straightforwardness of using the system (Fatoni & Surani, 2022). Social Influence (SI) indicates the impact of significant people on an individual's intention of adopting the system, while Facilitating Conditions (FC) represent the availability of external conditions from an organization that serves as a source of support for

the employment of the system (Fatoni & Surani, 2022). Social pressure can stem from a variety of sources including family members, teachers, peers, and co-workers and has been proved to have a significant influence on people's behavioral intention in academic studies (Ren, 2024).

2.4. Hypotheses

Prior studies conducted on the factors affecting the employment of AI tools in translation show a positive correlation between PEOU, PU, and learners' behavioral intention of adopting these tools (Almogren et al., 2024; Alotaibi et al., 2025; Ren, 2025), which corresponds to the traditional TAM theory. In this research context, behavioral intention construct has been omitted since Vietnamese students have been actively engaged in using ChatGPT for their translation tasks. Based on TAM theory and the context of the research, several hypotheses are formulated as follows:

H1: Perceived Usefulness (PU) positively impacts English majors' actual use of ChatGPT (AU) in translation.

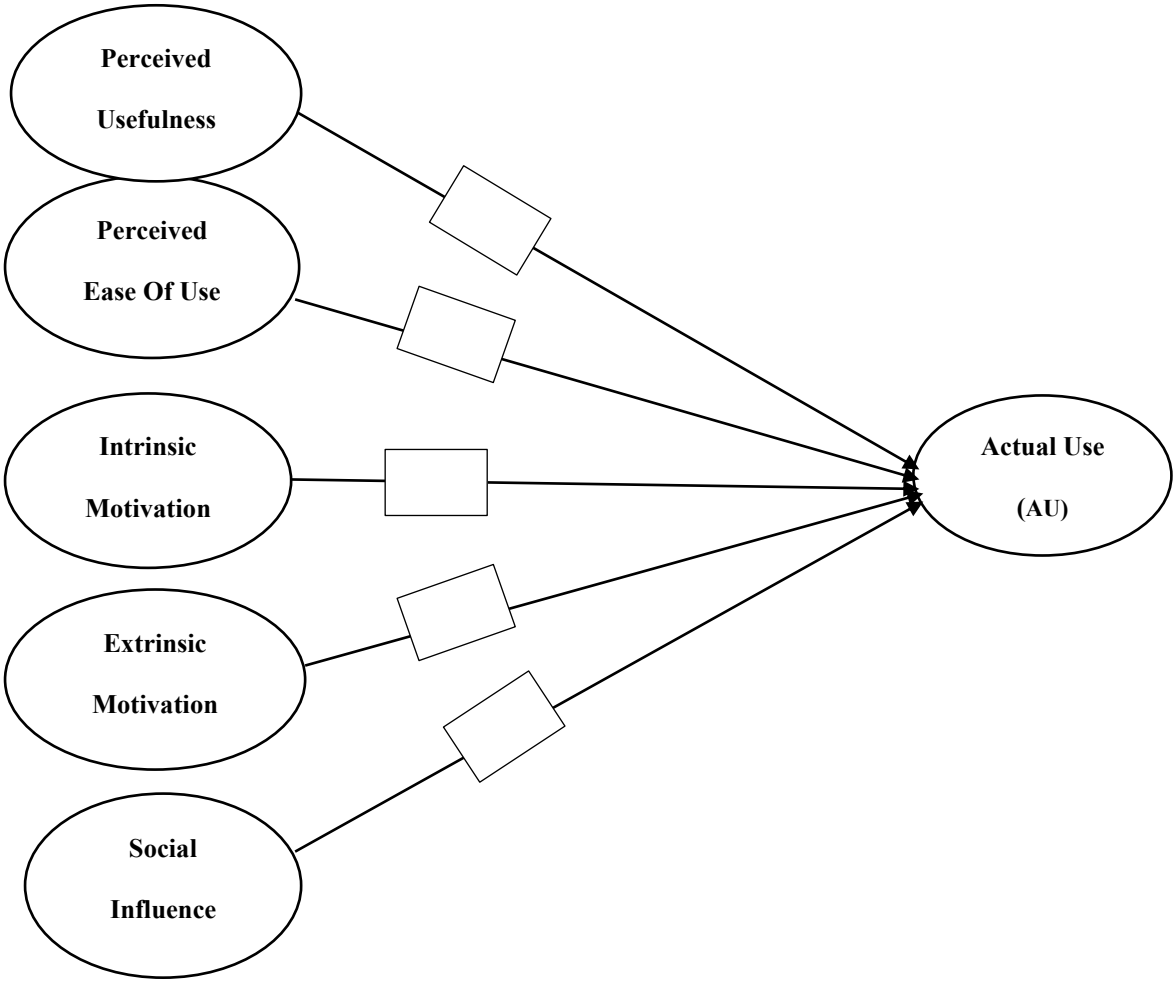
H2: Perceived Ease Of Use (PEOU) positively impacts English majors' actual use of ChatGPT (AU) in translation.

A few studies also found a positive connection between motivation and students' intent of using AI tools in translation (G. C. et al., 2024; Ren, 2025). The following statements are, therefore, hypothesized:

H3: Intrinsic motivation (IM) positively impacts English majors' actual use of ChatGPT (AU) in translation.

H4: Extrinsic motivation (EM) positively impacts English majors' actual use of ChatGPT (AU) in translation.

Social influence, or subjective norms, has been reported to beneficially influence learners' intention of using ChatGPT in language education, according to findings revealed by Almogren et al. (2024), Diep & Dang (2025), and Ren (2025). This entails the formulation of the last hypothesis:



H5: Social influence (SI) positively impacts English majors' actual use of ChatGPT (AU) in translation.

2.5. Conceptual Framework

The conceptual framework is then suggested as follows:

Figure 1

Proposed research model (Source: Researcher's proposal)

3. Methodology

3.1. Participants

The study involved 138 sophomores and juniors, specializing in a variety of majors at Ho Chi Minh University of Foreign Languages – Information Technology (HUFLIT); however, they are all required to take Translation 1 course. Below is the table illustrating the percentages of students in various majors.

Table 1

Participants' demographic information

Majors	Number	Percentage
Translation – Interpretation	15	10.9%
Business English	44	31.8%
English Pedagogy	59	42.8%
English for Office Administration	3	2.2%
English for Logistics	4	2.9%

English - Chinese Bilingualism	13	9.4%

3.2. Instruments

The study was implemented using a questionnaire and structured interviews with lecturers in charge of translation courses and English-majored students. The questions were drafted on Google Forms, and the link to this platform was distributed to groups of students via Zalo, while the interviews were also conducted online right after the completion of the survey. The questionnaire was composed based on such theoretical frameworks as Technology Acceptance Model theory, Self-Determination Theory, and Unified Theory of Acceptance and Use of Technology, and some of the questions were adapted to suit the context of Vietnamese classrooms. The questionnaire consists of nineteen items using a five-point Likert scale (Strongly Disagree, Disagree, Neither Agree nor Disagree, Agree, Strongly Agree) and is divided into diverse themes, namely Background Information, Perceived Usefulness, Perceived Ease Of Use, Intrinsic and Extrinsic Motivation, Social Influence, and ChatGPT Employment in Translation.

The interview sessions were carried out online with the involvement of eight students and four lecturers who have various years of experience in teaching translation courses at HUFLIT. The interviews consist of two questions for students and four questions for lecturers to elicit their perspectives on the employment of ChatGPT in translation teaching and learning.

3.3. Procedures

Subsequent to being drafted on Google Forms, the questionnaire was sent to groups of sophomores and juniors via Zalo through the shortened link obtained on Forms. The purpose of the study was carefully written in the survey to seek informed consent among the participants. Each interview session lasted from approximately fifteen to twenty minutes.

3.4. Data analysis

The data sheet, after being collected through responses on Google Forms, was downloaded and transferred to csv file before being coded to be ready to be imported in SMART-PLS 3.0 software program used for Partial Least Squares Structural Equation Modeling (PLS-SEM), an approach that examines the cause-effect relationship between latent variables, or between independent variables and dependent variables, in a model. These relationships are assessed through the measurement model, the structural model, and the confirmation of hypotheses. Out of 138 responses obtained from Google Forms, 131 responses are valid and used to be imported in the software program.

The interviews with four lecturers and eight students were transcribed and then analyzed using thematic analysis approach following the six steps proposed by Braun and Clarke (2006).

4. Results

4.1. Survey Results

4.1.1. Measurement model validation:

Scale Reliability & Validity Testing:

Table 2

Summary of coefficients in the PLS-SEM model

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)
AU	0.818	0.818	0.916	0.846
EM	0.796	0.809	0.880	0.711
IM	0.830	0.840	0.887	0.664
PEOU	0.798	0.803	0.868	0.623
PU	0.853	0.875	0.900	0.692
SI	0.773	0.780	0.867	0.685

Table 3

Outler loadings

	AU	EM	IM	PEOU	PU	SI
AU1	0.922					
AU2	0.917					
EM1		0.876				
EM2		0.773				
EM3		0.876				
IM1			0.875			
IM2			0.817			
IM3			0.835			
IM4			0.725			
PEOU1				0.723		
PEOU2				0.796		
PEOU3				0.803		
PEOU4				0.831		
PU1					0.853	
PU2					0.864	
PU3					0.735	
PU4					0.869	
SI1						0.826
SI2						0.839
SI3						0.818

Cronbach's Alpha (CA) & Outler Loadings: The results of Table 2 show that all construct coefficients are higher than 0.7, specifically ranging from 0.773 to 0.853, which means that all constructs achieve reliability. The findings also illustrate that the outer loadings (Table 3), which are used to assess the quality of the indicators, of all the factors are above 0.7, with the lowest being 0.723. According to Nunnally et al. (1994) and Ringle et al. (2013), these

results guarantee the reliability of all the indicators. Thus, all the variables ensure appropriate scale reliability.

Composite Reliability (CR): Table 2 indicates that the composite reliability of most constructs is greater than 0.8, with that of SI being 0.780, slightly lower than 0.8. Daskalakis & Mantas (2008) suggest when the composite reliability is higher than 0.8, the scale has good internal consistency. However, Henseler & Sarstedt (2012) maintain that CR > 0.7 is acceptable for a model with validation purposes. It can, therefore, be concluded that the internal consistency of the scale has been attained.

Convergent validity (AVE): Hair et al. (2017) prove that when AVE value is greater than 0.5, each construct explains more than half of the variance of its indicator. As can be seen from Table 3, the Average Variance Extracted (AVE) for all the constructs exceeds 0.5, ranging from 0.623 to 0.846, which indicates that each construct achieves good convergent validity.

Discriminant validity (HTMT):

Table 4

Discriminant validity (HTMT) according to the Fornell-Larcker Criterion

	AU	EM	IM	PEOU	PU	SI
AU	**0.920**					
EM	0.663	**0.843**				
IM	0.706	0.689	**0.815**			
PEOU	0.436	0.574	0.586	**0.789**		
PU	0.551	0.555	0.615	0.531	**0.832**	
SI	0.614	0.594	0.661	0.518	0.442	**0.828**

Table 5

Discriminant validity (HTMT) according to the Heterotrait-Monotrait Ratio

	AU	EM	IM	PEOU	PU	SI
AU						
EM	0.817					
IM	**0.853**	0.845				
PEOU	0.533	0.711	0.720			
PU	0.643	0.670	0.716	0.623		
SI	0.759	0.732	0.802	0.645	0.518	

The discriminant validity of the scale was measured using the Fornell-Larcker Criterion and the Heterotrait-Monotrait Ratio (HTMT).

According to the Fornell-Larcker Criterion, the discriminant validity is achieved when the square root of the AVE for any latent variable is higher than any other latent variable's variance. As indicated in Table 4, the discriminant validity of all the constructs is ensured since the square roots of the AVEs (bold and diagonal numbers) are higher than any correlations which are not diagonal.

The data in Table 5 suggest that the HTMT indices for all the pairs of first-order variables for most of the factors are below 0.85, which meets the standard of distinction proposed by Hair et al. (2016). Although the correlation between IM and AU reaches the 0.85 threshold, these are still lower than 0.9, which is an acceptable requirement for discrimination achievement.

Overall, based on the above-mentioned results, it can be said that the scale has ensured good reliability as well as validity.

4.1.2. Structural model assessment:

Multicollinearity Test:

Table 6

Variance Inflation Factor (VIF)

	VIF
AU1	1.916
AU2	1.916
EM1	1.971
EM2	1.461
EM3	1.938
IM1	2.410
IM2	1.832
IM3	1.973
IM4	1.477
PEOU1	1.388
PEOU2	1.513
PEOU3	1.824
PEOU4	2.055
PU1	2.083
PU2	**2.463**
PU3	1.830
PU4	2.260
SI1	1.780
SI2	1.892
SI3	**1.384**

Hair et al. (2017) measured multicollinearity, an issue which refers to the occurrence when there is a high correlation between independent variables, which leads to difficulty in the isolation of their individual impacts on a dependent variable, through Variance Inflation Factor (VIF). If VIF is higher than 0.2 or lower than 5, the independent latent variables do not encounter multicollinearity issues. As shown in Table 6, all the constructs have the VIF of

below 5, with the maximum value of 2.463 and the minimum of 1.384, indicating the absence of multicollinearity in latent variables.

Model Fit Validation:

Table 7

R and R^2 Validation

	R Square	R Square Adjusted
AU	0.594	0.577

The R square value or R^2 value was used to measure the model fit. According to Höck & Ringle (2010), if R^2 value is greater than or equal to 0.67, the explanatory power of the model is considered strong, while R^2 value ranging from 0.33 to 0.67 illustrates a medium power, and if the value is between 0.19 and 0.33, the model has a weak explanatory power. As presented in Table 7, R^2 value of the tested model is 0.577, which means it has a moderate explanatory power.

Table 8

f^2 Validation

	AU	EM	IM	PEOU	PU	SI
AU						
EM	**0.088**					
IM	**0.111**					
PEOU	**0.019**					
PU	**0.030**					
SI	**0.056**					

In this model, f^2 value was used to assess the extent of effect of each construct. Henseler & Sarstedt (2012) conclude that f^2 value is regarded as small, medium, and large if it corresponds to 0.02, 0.15, and 0.35 respectively. Table 8 shows that IM (0.111) has a medium effect, while PEOU (0.019) has a practically negligible impact, with the index being lower than 0.02.

Model Fit

Table 9

Model Fit Validation

	Saturated Model	Estimated Model
SRMR	**0.083**	**0.083**
d_ULS	**1.438**	**1.438**
d_G	**0.638**	**0.638**
Chi-Square	**492.021**	**492.021**
NFI	**0.701**	**0.701**

SRMR (Standardized Root Mean Square Residual) is a goodness-of-fit measure (GoF), which is adopted to measure the quality of the model. If SRMR is smaller than 0.08, the model achieves a good model fit (Hu & Bentler, 1998). The finding reveals that SRMR = 0.083, slightly greater than 0.08 but lower than 0.1, which is an indicator of an acceptable level of model fit.

Table 10

Q^2 Coefficient

	SSO	SSE	Q^2 (=1-SSE/SSO)
AU	262.000	137.631	0.475
EM	393.000	393.000	
IM	524.000	524.000	
PEOU	524.000	524.000	
PU	524.000	524.000	
SI	393.000	393.000	

Table 10 shows that the result of Q^2 coefficient, a value used to measure the level of forecast accuracy, demonstrates a high level of predictive accuracy. There are three levels corresponding to the value of Q^2 coefficient. If the value is between 0 and 0.25, the model has a low predictive relevance. If the value is greater than or equivalent to 0.25 and lower than or equal to 0.5, it is considered medium, and if the value exceeds 0.5, the forecast accuracy level is perceived to be high (Hair et al., 2016; Henseler et al., 2012). As presented in Table 10, the Q^2 coefficient is 0.475, illustrating that the model has a medium level of forecast accuracy.

4.1.3. Research Model Testing and Hypothesis Validation

Figure 2

Estimated model results using SMART PLS-SEM

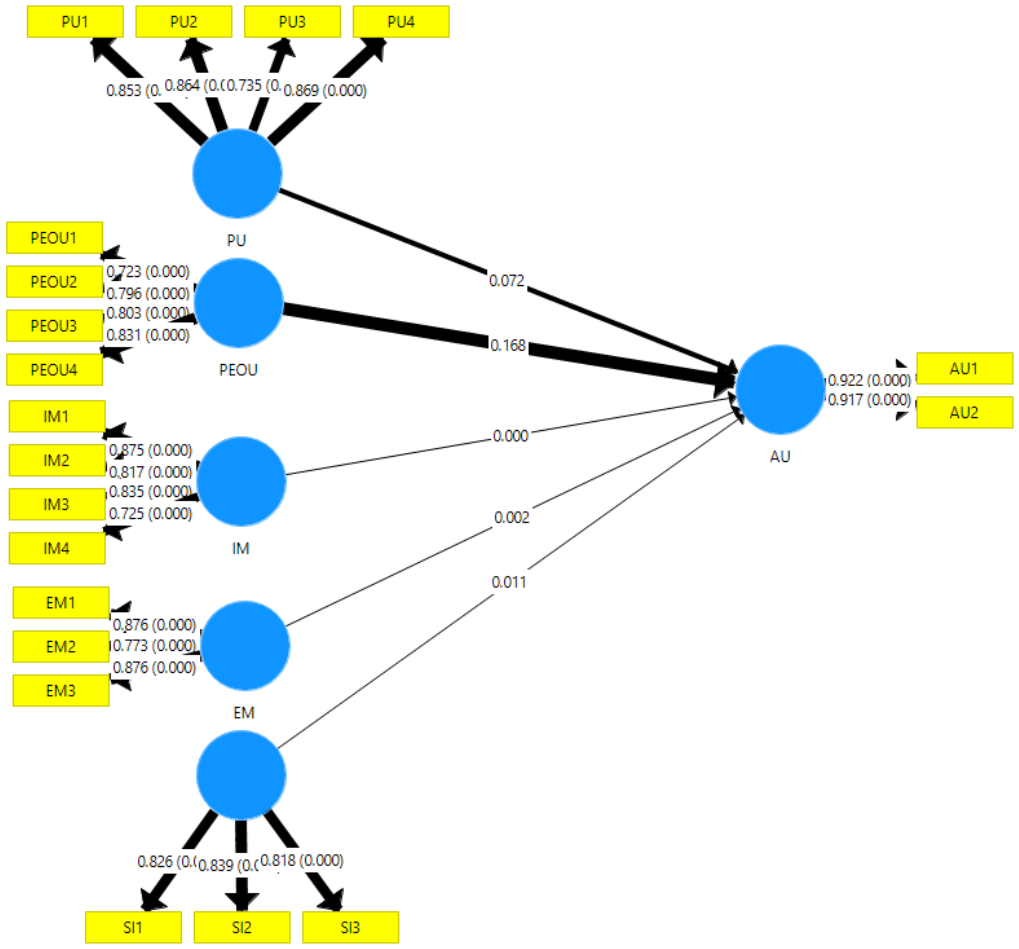


Table 11

Results of hypotheses testing

Hypotheses	Relationships	P Values	Results
H1	PU -> AU	**0.080**	**Rejected**
H2	PEOU -> AU	**0.192**	**Rejected**
H3	IM -> AU	0.000	Accepted
H4	EM -> AU	0.002	Accepted
H5	SI -> AU	0.007	Accepted

Probability value (P value) was employed to evaluate the fit of the structural model. According to Hair et al. (2017), the proposed hypothesis is accepted if P value is smaller than 0.05, and refutation of the hypothesis takes place when P value is greater than or equals to 0.05. Using Bootstrapping 1000, the results indicate that among the five proposed hypotheses, the hypotheses about the effects of IM on AU, EM on AU, and SI on AU are accepted (P values are below 0.05), whereas those of PU on AU and PEOU on AU are rejected (P values exceed 005). This means both intrinsic and extrinsic motivation have a positive impact on the actual employment of ChatGPT in translation, while Perceived Usefulness and Perceived Ease Of

Use exert a marginal or almost no impact on the actual use of this AI tool in textual translation, respectively.

4.2. Interview Results

The interviews with both English majors and lecturers were transcribed and then went through thematic analysis process to extract the most important themes to answer the formulated research questions.

4.2.1. Interviews with students

Three major themes emerged after interviews with eight randomly selected students were held. When asked what skills they should be explicitly taught in translation courses, most of the interviewees agreed on the teaching of linguistic knowledge, higher-order thinking skills, and post-editing competencies.

Theme 1: The consolidation of linguistic knowledge and skills in translation courses

Three out of eight interviewed students underscored the need to consolidate linguistic knowledge and skills for students taking translation courses since it provides a solid foundation for them to evaluate the precision and suitability of grammar and vocabulary use in a ChatGPT-produced translation and confidently correct the errors in the text. They also associated the possession of strong language skills with the capability of assessing the accuracy of meaning conveyed through lexical items and structures in the target language. They seemed to have been more aware of the importance of context and meaning in textual translation rather than the correctness of language use at a superficial level.

"Students need to have good reading comprehension skills and should trust their own abilities instead of relying too much on ChatGPT's translations."

"Students need critical thinking and language skills when using ChatGPT in translation courses. They should be able to check the accuracy of translations and edit them if necessary. For example, a student may use ChatGPT to translate a paragraph, then review the grammar and vocabulary to make sure the meaning is correct."

"*I think students need critical thinking and language knowledge. They should not rely on ChatGPT completely. Instead, they need to check whether the translation is correct and suitable for the context. For example, ChatGPT might translate a word correctly, but the meaning may not fit the situation, so students need to change it."*

Theme 2: The necessity of equipping students with higher-order thinking skills

Higher-order thinking skills are considered crucial skills that students in translation classes should be explicitly taught. This is especially important in the context of Vietnamese education where students have not had many opportunities to hone these skills due to exam-oriented curriculum and teacher-centered approach, to name but a few. Most of the participants suggested training different higher-order thinking skills such as critical thinking, evaluation, reasoning, comparison, researching, and independent thinking skills. Critical thinking, evaluation, and reasoning skills were repetitively mentioned in the students' responses, which indicates that they did not approve of the exclusive reliance on ChatGPT's translation but highlighted the role of learners in analyzing and criticizing the quality of the texts produced by ChatGPT, a process that is laborious and skills demanding. Only by mastering these skills can students evaluate the strengths and weaknesses of the tool, from which they are able to identify areas in need of improvement and make better-informed decisions related to ChatGPT-generated translation versions. Like in this student's response, she cited an example of the

phrase offered by ChatGPT and compared it with another phrase with the same correct meaning but more suitable in the context of Japanese culture. This proves the necessity of developing a critical mind coupled with prior background knowledge application in making lexical choices to convey the meaning of the original text.

"In addition, they should have critical thinking skills and the ability to search for and compare information from different sources in order to produce the best possible translation. For example, when translating the word "hoa đào," ChatGPT may translate it as "peach blossom." However, in some contexts such as Japanese culture, the correct translation should be "cherry blossom" (sakura). Therefore, students need to check the cultural context and compare different sources before deciding which translation is the most appropriate."

In agreement with the previous student, the following interviewee also highly valued the ability to think critically when it comes to translating culturally sensitive elements like idioms as ChatGPT's lack of cultural knowledge can hinder it from expressing the meaning of idioms naturally and accurately.

"I think students need strong critical thinking and post editing skills. We shouldn't just copy paste, instead we must be able to spot errors and refine the AI's output to make it sound more natural. For example, if ChatGPT translates a Vietnamese idiom literally, a student needs the skill to recognize that it sounds weird and change it to a more suitable English expression."

One student answered in the interview that the skill of most crucial importance was independent thinking skills. He asserted that students had better depend on themselves to handle the assignments, which is reflective of his consciousness of learner autonomy enhancement in translation, a requisite for lifelong learning. Self-reliance could not only free language learners from excessive dependence on ChatGPT, but it also helped stimulate their creativity and flexibility in idea construction.

"I think we have a clear example through the name. One is ChatGPT, and one is YOU. For that, the skill I think most required is do not let yourself be bound by a tool."

Theme 3: The significance of post-editing competencies in translation courses in ESL-oriented context

Five out of eight students stated that post-editing competencies should be incorporated into translation courses when they used a variety of lexical items such as "check," "change," "adjust," "edit," "spot errors," and "refine" to refer to the skills. ChatGPT is capable of coping with error detection and correction; however, the students thought they should be those shouldering this responsibility and to achieve this, they had to master the skills of post-edition. The process of post-editing a text requires a combination of competencies relevant to the comprehension and application of diverse linguistic aspects, identification of mistakes, knowledge of lexical and structural equivalents in the target language, and the ability to make prompt decisions in textual refinement, which can be nurtured through proper training.

"I think that students must have the ability to evaluate and reason when receiving information. For example, when receiving translation results, I would check and evaluate their accuracy and grammar. From there, I would adjust them to suit the target language."

Prompt engineering is also suggested as a necessary skill for honing as ChatGPT is formally used in translation courses. The student expressing this viewpoint said that prompts should be specific and precise to improve the tool's competence in generating translation versions that match learners' expectations. This response illustrates his recognition of the tool's limitations and the awareness of context and style attached to the texts.

"For example, instead of just saying "Translate this," a student should be able to command: "Translate this paragraph into academic English, using passive voice to enhance objectivity."

4.2.2. Interviews with lecturers

With regard to the question of how the adoption of ChatGPT has changed the way they teach translation subjects, the lecturers had differing opinions which could be divided into three themes.

Theme 1: Making transformations or adaptations to translation teaching.

Mindset change and role switching

Three out of four lecturers acknowledged that they had to transform their translation pedagogy once ChatGPT is formally incorporated into the curriculum, starting with a change in attitude towards the employment of ChatGPT in translation. They said that ChatGPT should be accepted as an integral part of the teaching and learning process instead of being banned from use; however, students should receive guidance on how to use ChatGPT appropriately. This change in mindset could be beneficial to students' linguistic development due to more frequent exposure to correct English, which may also improve their decision-making competency.

"My point of view is that in the current AI boom, instructors cannot and should not prohibit students from using ChatGPT to support their learning. Instead of prohibiting them, instructors should allow them, especially those studying Translation, to use apps they find necessary and effective for their learning."

Another transformation involves a shift in lecturers' role from those who traditionally act as knowledge providers to facilitators whose responsibility is to support and instruct students to critically evaluate ChatGPT-produced translations. Classroom activities, therefore, center around comparison and analysis of differences in linguistic and cultural elements between translations written by students and those produced from the chatbot.

"Instead of focusing only on traditional translation methods, I now integrate AI into classroom activities. For example, I ask students to compare their own translations with ChatGPT's output, then analyze differences in accuracy, tone, and cultural appropriateness. This has shifted my role from being the sole provider of answers to more of a facilitator who guides students in critical evaluation."

A respondent suggested that lecturers were expected to take on the role of linguistic scaffolders and monitors. To discourage students from excessive reliance on ChatGPT, lecturers should be more supportive in providing useful words, phrases, structures, collocations, and kindred issues while monitoring students' understanding and engagement in translation exercises in the classroom.

"Translation assignments usually have topics that align with the expectations of the course syllabus. Therefore, I will require students to grasp the topic first. Then, I divide the text into short paragraphs. Students will go to the board, only allowed to bring their textbooks, and translate the requested paragraphs. Students are not allowed to bring phones or other devices to the board. While one student is translating on the board, as an instructor, I suggest equivalent vocabulary or synonyms and especially equivalent grammatical structures to the class so that other students can create a similar or equivalent version. While students are translating on the board, the instructor checks their vocabulary and grammatical structures to

check their understanding of the text. For example, why is there ed in this phrase; why is which needed here; why isn't this sentence separated into two parts, etc."

Some of the lecturers also expressed their concerns over adaptations that should be made to translation teaching when English is turned into a second language at tertiary level. One lecturer felt that the integration of ChatGPT has enabled her to prioritize aspects like problem-solving and reflection in her lesson design process by encouraging her students to identify ChatGPT's areas of struggle in translation, particularly with idioms and specialist vocabulary.

"It also allows me to design lessons that emphasize problem-solving and reflection, such as identifying idioms or technical terms that AI struggles with."

Another interviewee admitted that she had to make use of blended teaching approach in her class, developing students' learner autonomy by giving them assignments for pre-class practice and requiring them to do in-class translation practice with the absence of AI tools.

"I have to change many activities which can help them remember the meaning and usage of vocabulary and structures in both languages. I have them translate the passages from the textbook at home before class time. I usually ask them to practice translating in class without AI tool or dictionary."

Designing more translation activities that promote interactivity, focus on meaning and context, as well as fostering students' critical translation and comprehension skills

Translation is usually considered a monotonous activity, so the incorporation of ChatGPT into the curriculum, from a lecturer's viewpoint, is likely to help increase interactivity among students in the classroom. According to another interviewee, games should also be introduced to boost memorization of new lexical items and structures as well as increasing interaction among learners.

Most of the interviewees agreed on the enhancement of students' critical thinking, decision-making, and evaluation skills through the organization of comparison, error analysis, reflection journals, and collaborative or group-based projects. Two lecturers stated that comparison exercises would likely benefit students in terms of linguistic accuracy, style development, and cultural awareness. Error analysis, reflection journals, and groupwork projects would sharpen students' evaluation and post-editing skills, reflecting on their improvements, and helping them value progress more than product.

"*One useful activity is comparison tasks, where students translate a text themselves and then compare it with ChatGPT's version, discussing differences in accuracy, tone, and cultural meaning. Another strategy is error analysis, where students identify mistakes in AI translations, such as idioms or technical terms, and propose better alternatives. Teachers can also design collaborative projects, asking groups to refine ChatGPT's draft into a polished translation, which encourages teamwork and critical thinking. Additionally, reflection journals can be used, where students record how they used AI, what they learned, and how they improved the translation. These activities help students see AI as a supportive tool, while still developing their own judgment and translation skills."*

A lecturer thought that translation lessons should encompass more activities devoted to sentence meaning and register rather than grammatical structures, which could assist learners to distinguish human translations from those produced by ChatGPT. It is the emphasis on meaning that can promote learners' recognition of their own importance in making their translations more easily distinguishable from machine-generated texts.

"... Lessons should not only focus on structures but the core meaning of sentences, and they should have a more focus on style of translation, which I think can differentiate human and machine's use of language and structures."

Despite this, one lecturer emphasized the importance of linguistic knowledge building, pointing out activities focusing on comprehension and translation skills such as figuring out, applying synonyms, opposites, collocations in contexts, and answering guided questions had better be consolidated during class time.

"[...] find synonyms, find antonyms, find equivalent structures, find collocations of keywords in the lesson, put the collocations in contexts or sentences. At the beginning of the lesson, the teacher asks students about vocabulary learned in the previous session."

She specified that these activities could provide a solid foundation for students to gain a deeper understanding of word and structure usage, thereby enhancing their comprehension skills.

"When the student can answer the instructor's questions, the AI-based reference is considered effective. Conversely, if the student only knows how to write the translation on the board without understanding the instructor's why questions, their AI-based look-up is considered rote learning and ineffective reference."

Theme 2: Skills that students of translation courses should be equipped with

The four lecturers who attended the interviews suggested a diversity of skills on which students should receive explicit instruction in translation classes. They perceived the foundational skills students should master to be lower-thinking and translation skills, insisting that students had better remember the vocabulary and grammar patterns acquired and should be able to apply them in sentences. They believed learners should also be provided training on how to effectively utilize such strategies as thematic or topical understanding, paraphrasing, simplification of complicated ideas, appropriate employment of register in translation during the courses. Other skills they mentioned are higher-order thinking skills, enhanced awareness of context and cultural nuances, and post-editing competence. They maintained that critical evaluation ability for textual precision and meaning allows students to assess the translated texts objectively before making any relevant adjustments, whereas detecting ChatGPT's weaknesses in literary translation and cultural subtleties helps improve learners' judgement, and post-editing competency can result in the best possible translation versions. Crafting prompts, from the perspectives of two lecturers, is also an essential skill that will likely aid students in requiring ChatGPT to generate much better results tailored to their requirements.

"The following can be explicitly taught as related skills: how to grasp the theme of the text, how to translate concisely, how to create equivalent structures, how to rephrase or simplify complex ideas, how to put the collocations in contexts or sentences, how to improve formality using appropriate styles or nuances in different contexts, and how to have a better version."

"Students can be explicitly taught several key skills when ChatGPT is formally integrated into translation courses. First, they need critical evaluation skills, learning how to check AI translations against the source text for accuracy and meaning. Second, editing and revision skills are important, so students can refine AI outputs to match academic or professional standards. Third, they should practice cultural and contextual awareness, recognizing when AI struggles with idioms, metaphors, or culturally specific expressions. Finally, prompting skills can be taught, showing students how to give clear instructions to AI

for better results. For example, a student might ask ChatGPT to "translate this text into formal academic English" rather than just "translate," which produces more precise outcomes. These skills ensure students use AI responsibly while still developing their own translation competence."

Theme 3: The types of pedagogical instructions or strategies that could be incorporated into translation teaching when ChatGPT becomes a formal tool for teaching and learning English

Pedagogical instructions on ChatGPT adoption

All the lecturers held the belief that students should be provided with pedagogical guidance on AI adoption. On the one hand, students should be officially informed of the acceptance of ChatGPT as a supportive tool in the classroom, which means the tool can be utilized to improve their linguistic competence. On the other hand, they had to conform with some regulations in tests and assessment where AI tools were restricted, and they were expected to maintain self-reliance in exams. Furthermore, students should be instructed to write prompts more effectively to meet their demands and the objectives of the unit. This kind of AI literacy training can help students gain deeper insights into their translation tasks, especially in terms of specialized words, styles, and cultural variations, while cultivating a sense of critical thinking, analytical judgement, along with learner autonomy.

"*When my students intend to use ChatGPT in their translation exercises, I usually give them clear instructions to guide their practice. First, I remind them to use ChatGPT as a support tool, not as a substitute for their own thinking."*

"Announcing that students are allowed to use translation tools when doing assignments such as classwork, homework, Moodle assignments, and emphasizing that in the mid-term and final exams, students must rely on themselves. Clarifying that any assistance from translation applications or tools used in the exam room will be considered cheating. Informing learners that translation tools are merely supporting tools, while learners themselves must learn various translation methods to create as many versions as possible, with the ultimate goal of boosting translation skills."

Instructions on ethical use of ChatGPT

The second type of instruction suggested by the lecturers is raising ethical awareness in adopting ChatGPT among learners by specifying that they were supposed to use ChatGPT in a responsible manner and be conscious of biases and other sensitive issues arising from the employment of this AI-assistant tool since increased awareness of these problems can prevent them from exhibiting a distorted view of other cultures or languages.

"In the middle of the course, I train my students how to use AI tools effectively and discuss with them about ethical issues. Specially, they need to evaluate the AI translation and be responsible for their final translation version."

"... I mean, they'd be able to manually check for accuracy and identify biased results, and beware of several ethical issues such as privacy, security and sensitivity of generated data."

Instructions on development of learner autonomy

Despite permitting the employment of ChatGPT for linguistic practice, the lecturers expected their students to be actively and critically engaged in translation tasks through comparison and contrast of their own translations with those of ChatGPT, accuracy check, and

revision of ChatGPT-generated versions. In addition, they ought to be involved in decision-making process and take advantage of translation methods and skills to produce multiple translations. This implies the prioritization of enhancing translation competence and judgmental independence, which were crucial factors contributing to enhanced learner autonomy.

"... They should compare the AI's translation with their own draft, then analyze differences in word choice, grammar, and style. Second, I encourage them to check accuracy by reading the original text carefully and asking whether the AI output truly reflects the meaning. For example, if ChatGPT translates an idiom literally, students must decide whether to keep it or adapt it to natural Vietnamese or English usage. Finally, I ask them to revise the AI-generated text to match academic standards, because translation is not only about meaning but also about tone, context, and appropriateness. This way, they learn to use AI critically and responsibly."

5. Discussion

This research paper attempts to seek answers to the following questions:

RQ1: What are the factors influencing English-majored students at HUFLIT to adopt ChatGPT in their translation courses?

Regarding the first research question, the quantitative data obtained from SMART PLS 3 reveals that the greatest contributory factor to the actual adoption of ChatGPT in translation is intrinsic motivation, closely followed by extrinsic motivation, and social influence. This finding is consistent with that of the research undertaken by Ren (2025). Surprisingly, Perceived Usefulness and Perceived Ease Of Use have little or no significant impact on the actual use of ChatGPT in translation, which is contrary to prior studies whose findings have confirmed the positive influence of these factors on behavioral intention and the actual use of a technological tool (Almogren et al., 2024; Alotaibi et al., 2025; Ren, 2025).

It seems that internal factors are the key determinants driving English majors' use of ChatGPT for translation purposes rather than external utility or ease of use in Vietnamese classrooms. This is justifiable since these surveyed participants are GenZ students, or commonly known as the app generation, who have become accustomed to the use of technological devices such as smartphones and laptops. The use of AI-powered tools like ChatGPT to facilitate language learning has become a social norm in their educational environment; thus, the extent of simplicity or usefulness of the tool does not significantly influence the adoption of this AI assistant tool. According to traditional TAM theory, the straightforwardness of technological adoption is proportionate to the degree of using it; nevertheless, this belief seems no longer true in this context. GenZ students are digital natives, so exploiting a piece of technology is relatively easy for them, particularly when they are studying in an environment conducive to technological developments. This leads to an inconsiderable effect of PEOU on the students' use of ChatGPT in translation.

More importantly, intrinsic motivation such as pleasure or interest is the leading factor behind the students' actual employment of ChatGPT. The Vietnamese students are internally motivated to experiment with the tool in translation perhaps because they find it intriguing to explore the tool's capabilities in a demanding subject, or they feel a sense of fulfillment derived from adopting the chatbot since they can accumulate valuable linguistic knowledge and skills through ChatGPT's offer of diverse translation versions with a wide range of word choice and sentence construction. Another significant determinant behind the chatbot use is extrinsic motivation which is often manifested under different forms of outcome gains such as grades

and rewards. Vietnamese education system is exam-oriented and achievement-driven, and so expectations on attaining high academic performance have been deeply ingrained in generations of Vietnamese students' mentality. The use of ChatGPT can not only allow them to relieve the mounting exam pressure, but it can boost their scores or aid them in accomplishing the desired targets as well.

Social influence is also a factor positively driving students to utilize the tool. The role of this factor has been confirmed in the studies conducted by Almogren et al. (2024), Diep & Dang (2025), and Ren (2025). In a collectivist society characterized by a strong bond between people like in Vietnam, teachers and peers are those whose words of encouragement can change a student's behavior. Moreover, teachers are often seen as revered authority figures who can strongly shape students' attitude and actions, while students tend to follow peers' example, especially who are highly competent, to utilize a piece of technology that is likely to boost their scores or academic success whether it is simple to use or not. That is why social influence has made a positive impact on the students' actual adoption of ChatGPT.

RQ2: What skills can be explicitly taught to English-majored students as ChatGPT is formally integrated into translation courses?

With respect to the second question, from the viewpoints of the students, their linguistic competency should be enhanced so that they can confidently handle issues related to the exact usage and contextual appropriateness of lexical units and grammar patterns to convey the original meaning of the language in translations produced by ChatGPT. Apart from this, the students are also expected to receive explicit instructions on how to foster their higher-order thinking skills and post-editing competence in translation courses. These views are supported by lecturers who also stress the significance of lower thinking and translation skills. They maintain that foundational strategies such as recall and application should accompany translation skills such as linguistic ability, cultural and contextual awareness, topical expertise, and techniques like rewording, text simplification, and register use. These findings are in alignment with translation competence model and metacognitive theory. Translation competence, developed by the PACTE group in 2003, is defined as the capability of translating textual information with skills and expertise knowledge (Wilss, 1996, cited in Salamah, 2021) encompassing five elements, namely "language competence, textual competence, subject competence, cultural competence, and transfer competence" (p. 279). Meanwhile, metacognition is an indispensable part of translation competence, in which learners are required to think about the topic in advance as well as reflecting on it during the learning process (Posner et al., 1982, cited in Yanqun, 2015). Yanqun (2015) asserts that this kind of reflection can greatly assist students to achieve academic success as they can look back at their experiences, learning activities, and decisions for in-depth analysis to identify areas for improvement so that they are able to perform better in their future learning paths. In the research context, it is observed that Vietnamese students often struggle with translation due to their limited size of lexeme and grammar knowledge as well as weaknesses in applying diverse skills to translation. The frequent adoption of AI tools can lead to more constant exposure to accurate English; however, they should have their knowledge and translational skills consolidated to double-check the quality of ChatGPT-generated translations, from which they can refine the texts on their own. This matches well with the content of the translation competence model and metacognitive theory discussed above.

RQ3: What kinds of pedagogical instructions or strategies could be incorporated into translation teaching when ChatGPT becomes a formal tool for teaching and learning English?

In terms of the types of pedagogical instructions that can be integrated into translation teaching when ChatGPT becomes a formal tool for language education, the lecturers suggest providing specific, transparent guidance on how to utilize the chatbot appropriately and productively for self-study and in-class practice along with imposing strict constraints on its adoption in tests and forms of assessment. This is justifiable since an increased reliance on AI-powered tool is bound to undermine students' translation competence, and this can be even worse in the context of Vietnam where expectations for outperformance in exams are often appreciated at the expense of critical thinking skills and judgmental capability development. Simultaneously, it is lecturers who should promote students' autonomy and accountability for using ChatGPT, helping them recognize biases and other relevant ethical issues. These concur with that indicated by Almogren et al. (2024) who underscored how ChatGPT could be utilized in a more responsible and ethical manner in educational settings.

When it comes to pedagogical strategies, the lecturers who attended the interview believe that mindset change and role shifting are essential transformations they can make to benefit students' translation learning process. Embracing the utilization of ChatGPT in translation instead of prohibiting it will allow better decision-making skills among students, while lecturers acting as a facilitator or scaffolder can help learners bridge the gaps in their knowledge and skills through guided questions. Adaptations to the lesson content such as interaction enhancement and incorporation of context and meaning-focused activities, as well as those cultivating critical translation and comprehension skills should be made once ChatGPT has been formally integrated into translation courses. The underlying reason for this is translation classes in Vietnam is often teacher-centered, characterized by lecturers transferring knowledge and students passively involved in the lessons. The addition of more interactivity-boosting activities can bring fresh air to the class, changing its focus to a more student-centered one, which in turn encourages learners to take a more active role. Translation is not only mechanically conveying the meaning of the original sentences in the target language, but it also includes analyzing and understanding the sentence meaning and its context in depth, and to achieve this objective, students need to dynamically participate in a variety of tasks requiring critical evaluation, error judgement, reflection, and collaboration. More importantly, students' ability to acquire a language could be greatly enhanced through conversations with their teachers and peers. This finding ties well with sociocultural theory proposed by Vygotsky (1978) and scaffolding technique, which is an integral part of the Zone of Proximal Development model (ZPD). In the words of Vygotsky (1978, cited in Lee, 2015), students' language acquisition process is mainly constructed through their interactions with peers and teachers, and this belief, together with the Zone of Proximal Development model (ZPD), emphasizes the accomplishment of learning under guidance of teachers or through communication of learners with those who are more knowledgeable than them in a specific discipline (Alghamdy, 2023; Muntasir & Akbar, 2023). In the meantime, scaffolding technique revolves around teachers' provision of assistance or pedagogical instruction to students, with the aim of fostering their engagement in learning (Sarmiento-Campos et al., 2022). According to these researchers, scaffolding means more than mere ordinary support, but specific, accurate support given promptly can become a source of motivation leading to an increase in active involvement among learners. Vietnamese students are inclined to be reserved, so constructive support from their teachers or more capable friends are of great benefit to them. Taking on the role of an academic guide or a scaffolder enables teachers to keep track of their students' progress and implement meticulous plans for students' knowledge reinforcement.

Implications for Vietnam's ESL Transition

- **Educators**

Lecturers should add elements of interactivity to lessons to enhance students' engagement during the course. They should switch to the role of a scaffolder or facilitator to maximize students' learning productivity since merely letting them depend on the tool does not guarantee academic progress as they still struggle with a diversity of linguistic aspects that they are not competent in. Group-based projects and student-centered or peer-supported activities could be leveraged to increase the use of ChatGPT in translation due to the strong influence of capable peers on others. However, educators should also design lessons nurturing students' fundamental linguistic knowledge, translation skills, higher-order thinking skills, and post-editing competence so that students have the capability of translating the assigned texts individually with great confidence.

- **Curriculum design**

The research findings imply that curriculum design for translation courses in Vietnamese ESL-oriented context could place an emphasis on enhancing motivational factors among students since these significantly influence the use of ChatGPT in translation. Both intrinsic and extrinsic motivation are closely intertwined and contribute to the degree of actual employment of the chatbot. Curriculum designers, therefore, need to be fully aware of the impact of these factors to incorporate modules encouraging students to use the AI-powered tool with genuine interest or pleasure since stimulation of authentic interest can result in a more active attitude, which entails deeper learning. Making them understand the real value of intrinsic motivation in academic studies could also free them from excessive reliance on the tool for external benefits, thereby gearing them towards viewing translation learning as a worthwhile experience. Employment benefits should be emphasized to serve as external motivation for increasing the adoption of AI tools as well. If the students are well informed about the increasing demand for technological literacy in the labor market, they will be more motivated to utilize AI-powered tools to land a high-paying job.

Separate modules on higher-order thinking skills and post-editing competency should also be integrated into translation courses to provide students with training on how to draft effective prompts and critically evaluate a piece of translation for better error identification and rectification, specifically when it is pertinent to cultural or contextual subtleties. Indeed, when English has become a second language for instruction in tertiary education settings, the capabilities to analyze and judge textual translations produced by AI tools with a critical eye seem to be of paramount importance, which may help differentiate AI-generated versions and those written by humans.

6. Conclusion

The factors influencing English-majors' employment of ChatGPT in translation have been examined using SMART-PLS 3 and structured interviews in this research paper. The study results reveal the varying effects of Perceived Ease Of Use (PEOU), Perceived Usefulness (PU), Intrinsic and Extrinsic Motivation (IM and EM), and Social Influence (SI) on the students' adoption of ChatGPT in translation courses. While IM, EM, and SI positively affect the use of ChatGPT, PU and PEOU are found to exert an insignificant or practically no impact on the students' employment of this AI assistant tool. The findings also suggest that lecturers in charge of translation subjects should transform or adapt their translation pedagogies through a change in mindset and role as well as an incorporation of activities with a greater focus on interaction, meaning, context, critical translation, and comprehension skills. The study also places an emphasis on the equipment of translation, linguistic knowledge, lower-thinking

and higher-order thinking skills, an increased awareness of contextual and cultural subtleties, as well as post-editing competence for English majors. However, lecturers should provide students with appropriate pedagogical guidance concerning the acceptance of ChatGPT adoption in classrooms for linguistic development and guarantee the imposition of restrictions on its use in exam conditions, along with consciousness raising of related ethical issues in employing the chatbot.

Limitations

The study reveals some limitations, with the first being the sample size. With a larger sample size, the obtained results would be more generalizable, thereby increasing the validity and reliability of the findings. Another shortcoming is the employment of structured interviews in the study could limit in-depth insights into the participants' perspectives on the research questions.

Recommendations for further studies

Further studies should consider the influence of a mediating variable on the relationship between the above-mentioned factors, especially Perceived Usefulness, and the actual use of ChatGPT in translation. Within the research context, the correlation between PU and AU is not significant, which contradicts the findings of previous studies.

Bionote

Huong Thi Thu Le is currently an experienced lecturer working for the Faculty of Foreign Languages, HUFLIT, Vietnam with more than twelve years of teaching experience. She earned a bachelor's degree from Ho Chi Minh University of Education and holds a master's degree in TESOL from Victoria University. Her interests are primarily novel methodologies to enhance students' learning and achievement, AI tools, and how these can make radical improvements in learners.

Appendices

Appendix A: Questionnaire

EXAMINING THE FACTORS AFFECTING THE EMPLOYMENT OF CHATGPT IN TRANSLATION AMONG ENGLISH-MAJORS AT HUFLIT AS VIETNAMESE EDUCATION TRANSITIONS FROM EFL TO ESL ORIENTATION

Dear students, I am conducting a study to investigate the factors behind the adoption of ChatGPT in translation among English majors at HUFLIT as Vietnam shifts from an EFL to ESL-focused education. I would love you to spend some of your time completing this survey, which should last approximately 10 minutes. I am sure that your responses are kept completely confidential. Thank you very much for your participation.

SECTION 1: BACKGROUND INFORMATION

Email Address

Which gender are you?

- o Male
- o Female
- o Prefer not to say

Which major are you in?

- o Translation - Interpretation
- o Business English
- o English Pedagogy
- o English for Office Administration
- o English for Logistics
- o English - Chinese Bilingualism

Have you ever used ChatGPT for translation exercises?

- o Yes (Move to the next question)
- o No (You can stop here. Thank you for your participation)

How often do you use ChatGPT in translation subjects?

- o Always
- o Usually
- o Sometimes
- o Seldom

SECTION 2: PERCEIVED USEFULNESS OF CHATGPT

Rate the following statements on the perceived usefulness of ChatGPT on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5

1	ChatGPT enhances my performance in translation courses.					
2	ChatGPT's customized feedback helps me improve the accuracy of translated texts.					
3	ChatGPT gives me multiple options of vocabulary, grammar, and idea expressions, which helps improve the quality of my translations.					
4	ChatGPT assists me to complete translation exercises more effectively.					

SECTION 3: PERCEIVED EASE OF USE

Rate the following statements on the perceived ease of use of ChatGPT on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5
1	ChatGPT's interface is user-friendly, making it easy for me to use it for translation tasks.					
2	Responses from ChatGPT to my requests are clear and understandable.					
3	Giving prompts to ChatGPT to translate texts is simple.					
4	I find it simple to learn how to use ChatGPT for translation exercises.					

SECTION 4: MOTIVATION BEHIND THE ADOPTION OF CHATGPT

INTRINSIC MOTIVATION

Rate the following statements on the intrinsic motivation behind the employment of ChatGPT on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5
1	I find it interesting to use ChatGPT for translation assignments.					
2	Adopting ChatGPT enables me to take greater control of my translation learning.					
3	I enjoy using ChatGPT to generate different translation versions.					
4	I am curious to find out how ChatGPT can assist me with translation work.					

SECTION 5: MOTIVATION BEHIND THE ADOPTION OF CHATGPT

EXTRINSIC MOTIVATION

Rate the following statements on the extrinsic motivation behind the employment of ChatGPT on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5
1	I use ChatGPT to achieve better results in translation courses.					
2	Adopting ChatGPT helps me reduce workload pressure in translation courses.					
3	I can better cope with assessment requirements thanks to the use of ChatGPT.					

SECTION 6: SOCIAL INFLUENCE

Rate the following statements on the social influence of using ChatGPT in translation on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5
1	People who are important to me think I should employ ChatGPT for translation.					
2	My lecturer encourages me to use ChatGPT in translation.					
3	I feel I am influenced to adopt ChatGPT for translation assignments by my peers.					

SECTION 7: CHATGPT EMPLOYMENT IN TRANSLATION

Rate the following statements on ChatGPT employment in translation on a scale of 5 (1 = Completely Disagree; 2 = Disagree; 3 = Neither Agree nor Disagree; 4 = Agree; 5 = Completely Agree)

No.	Statements	1	2	3	4	5
1	I frequently use ChatGPT when handling translation assignments.					
2	I rely on ChatGPT as a tool for supporting my translation work.					

Appendix B: Interview Questions

FOR STUDENTS

1. What kind of translation assignments do you often use ChatGPT for?
2. What skills do you think are required among students of English when ChatGPT is formally used in translation courses? Can you give me an example?

FOR LECTURERS

1. What types of instruction do you often give to your students who intend to use ChatGPT in their translation exercises?
2. How has the students' adoption of ChatGPT changed the way you teach translation subjects?
3. What kinds of activities or strategies do you think can be incorporated into translation teaching when ChatGPT becomes a formal tool for teaching and learning?
4. What skills can be explicitly taught to students as ChatGPT is formally integrated into translation courses?

#48 Investigating Students' Perspectives and Engagement Levels with AI Tools in Second Language Acquisition (SLA) Courses

Lan DoThi

Abstract

In the fast-growing digital era, the integration of Artificial Intelligence (AI) tools has become indispensable in higher education, particularly in language studies where these technologies offer personalized linguistic support and cognitive scaffolding. Despite this prevalence, empirical evidence regarding student engagement in specialized subjects like Second Language Acquisition (SLA) remains limited. This study employs a quantitative and qualitative approach, surveying 125 fisrt-year students at HUFLIT upon their course completion to examine their perspectives and usage patterns of AI applications. Data analysis, conducted via Microsoft Excel, reveals a profound correlation between student learning habits and digital tool engagement, indicating that learners increasingly rely on AI for conceptual clarity and task execution. The findings suggest that AI tools are no longer optional, but they are seen as central to the modern learning experience. Consequently, it is recommended that educators proactively update their pedagogical strategies to align with these digital trends. If properly adopted, embracing AI-driven methodologies will support instructional efficacy in teaching and foster a more responsive, tech-integrated environment for second language learners.

Key words*: Second Language Acquisition (SLA), strategies, applications, AI-driven, efficacy*

Abbreviations:

SLA: Second Language Acquisition

AI: Artificial Inteligence

Q: Question

L1: First Language

L2: Second Language

I hereby formally confirm my commitment to serve as a speaker at the HUFLIT INTESOL INTERNATIONAL CONFERENCE 2026 conference. I acknowledge that failing to uphold this commitment without valid prior notice will result in my exclusion from participation in the next two consecutive HUFLIT INTESOL conferences.

1. Introduction

1.1. Rationale for choosing the research topic

With the trend of integration and globalization, language learning has become a necessity today. The languages we teach will face a major challenge: the emergence of artificial intelligence (AI). In the digital age AI is a transformative force, driving efficiency and innovation across all sectors. In other words, AI is no longer a luxury but a necessity; it provides personalized paths, instant feedback, and immersive environments that traditional teaching methods often lack. By leveraging AI tools, learners can achieve fluency faster, bridging cultural gaps and mastering Second Language Acquisition (SLA) with unprecedented precision

and scale. However, certain difficulty in learning SLA as a subject for the first-year students at Huflit may raise a question.

While previous studies have extensively discussed the technical capabilities of AI, there remains a critical research gap regarding the human element. This study, by investigating students' perspectives and engagement levels with AI tools in Second Language Acquisition (SLA) courses, seeks to uncover the subjective experiences that determine how effective these tools are in the SLA classroom.

1.2. Research Objectives

This research aims to comprehensively evaluate the integration of Artificial Intelligence (AI) among first-year students within the context of Second Language Acquisition (SLA). Specifically, the study seeks to investigate students' attitudes toward AI-driven tools, examining their perceptions of usefulness and ease of use. Furthermore, it analyzes the specific behaviors and engagement patterns exhibited by learners during the language learning process. Ultimately, the research assesses the effectiveness of these technologies in improving linguistic proficiency and learning outcomes. By synthesizing these three factors, the study provides critical insights into how AI can be optimized to enhance foundational language education in the digital era.

1.3. Research questions

To achieve the research objectives, the following three core questions have been formulated:

(1) What are the perceptions and attitudes of first-year students toward the integration of AI in SLA?

(2) What are the predominant AI tools and usage patterns exhibited by these students in their language learning routines?

(3) To what extent do first-year students perceive AI as effective in enhancing their linguistic proficiency and overall learning outcomes?

1.4. Scope of Research

The research subjects are first-year students at Huflit University. They are first-year students who have just finished the course titled "An Introduction to SLA". Each class has approximately 70 students. However, 125 was the total number of respondents in the two classes surveyed at the end of the course.

2. Literature Review

2.1. SLA and the significance of technology

2.1.1. Definition of SLA

According to Benati & Angelovska (2016), SLA is the study of how learners create a new language system despite an often-limited exposure to the second language/foreign language learning contexts. In a general sense, a second language (L2) refers to a language that is acquired after the first language (L1) has been established in early childhood.

SLA addresses two fundamental questions: (1) how learners come to internalize the linguistic system of another language; (2) how learners make use of that linguistic system during comprehension and speech production (Benati & Angelovska, 2016).

The following are distinctions commonly made in literature:

"A second language" is typically an official or societally dominant language needed for education, employment, and other basic purposes. It is often acquired by minority group members or immigrants who speak another language natively. In this more restricted sense, the term is contrasted with other terms. However, the term "a foreign language" is one not widely used in the learners' immediate social context which might be used for future travel or other cross-cultural communication situations or studied as a curricular requirement or elective in school, but with no immediate or necessary practical application (Saville-Troike & Barto, 2017).

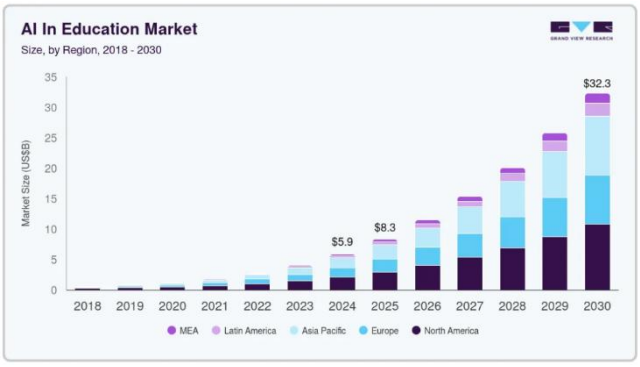
2.1.2. SLA learners' purposes

There are six broad groups of L2 users: People who are part of multilingual communities; People regaining their cultural heritage, short-term visitors to another country; People using an L2 with partners, friends or children; People using an L2 internationally for specific functions and People using an L2 internationally for a wide range of functions (Cook & Singleton, 2014).

The learner's purpose in acquiring the L2 in some cases is not related to long-term integration only, but has more practical, short-term goals - such as meeting a requirement for school or university matriculation or graduation, applying for a job, or gaining access to material in the second language (Cook & Singleton, 2014).

The use of a language - whether first or second - has as its goal the communication of ideas, maintenance of social relations, and creation of discourse, all of which require the development of several core competencies. These include input competencies, such as listening and reading, and output competencies, such as speaking and writing, and entail the process of receiving (input), attending to (interaction), and assigning meaning (output) to verbal (aural or written) and/or visual stimuli. They also include competencies in communicating in the target language, which includes an understanding of the cultural context of such communication (Jones, 2014).

2.1.3. The Impact of Technology as Mediator of SLA Processes



In teaching, especially language teaching, adopting technology properly as a language input is expected by both intructors and learners. The enhancement of learning outcomes is practically possible since "technology allows for exposure to authentic target language input, in the form of multimodal websites that contain text-based, audio, and video information about both language and culture. In addition, many different types of Computer-Mediated Communication, often classified as Web 1.0 and Web 2.0 technologies (e.g., email, forums, chats, blogs, wikis, podcasts, videos, social networking sites, virtual worlds, massively multiplayer online games) enable various kinds of communication, interaction, and collaboration" (Chun, 2016).

2.2. AI when used in Education

2.2.1. Advantages of AI tools in education

It is undeniable that AI tools have proven their advantages, not only from the teachers' perspective but also from the learners'. Tseng & Warschauer (2023) claimed: "Even if we could ban AI from education, we shouldn't. ChatGPT and similar tools offer powerful affordances for second language learners that should not be discounted".

Looking at this chart, what we can see is the irrevesable trend. The global AI education market is predicted to exceed $32.3 billion by 2030. What we may infer is that these are not simply forecast figures, but rather an assessment of a global development trend.

Source: Grand View Research, AI In Education Market Sise & Share

The question is whether we may use AI as effectively as we wish, or will AI somehow influence our teaching, change learners' perspectives, and force us to adapt our teaching methods to keep pace with the rapid development of AI and its applications.

In terms of accessibility and functionality, there are clear advantages that these tools can offer. According to AIT (2023), if we apply AI Chatbot in education, AI Chatbot will act as an assistant, helping teachers with many time-consuming tasks such as imparting knowledge, grading, guiding students to solve some basic exercises, storing information about scores, and monitoring students' learning progress. ChatGPT's writing style is concise, smooth and very natural. The answers are written neatly and concisely, without spelling mistakes. Learners must be smart to rely on ChatGPT to exploit the Bot to bring positive benefits to themselves (An, 2023).

ChatGPT can affect several aspects of education, including writing, instruction methods and teaching pedagogy (Javaid et al., 2023). Aktay et al. (2023) believe that ChatGPT is its ability to respond rapidly. Education and AI are critical topics of conversations about the future of our society.

According to Rahman and Watanobe (2023), ChatGPT can help students solve complex problems. One of the most powerful features of ChatGPT is its human-like understanding and response. Learners can now ask ChatGPT questions in the same way as they would ask their tutor. From elementary school to higher education and professional development, it can be used at all levels of education. However, ChatGPT's extraordinary ability to perform complex tasks in the education field has sparked controversy while some are considering ChatGPT and AI to be the future of teaching and learning, as well as educational research (Baidoo-Anu & Ansah, 2023). Rasul et al., (2023) claimed that as ChatGPT continues to improve and evolve, it is likely to become an increasingly important tool for researchers and scholars and promises to be a potential application for integration into education in the coming years.

Karanjakwut and Charunsri (2025) pointed out that before the introduction of ChatGPT, traditional brainstorming was still a widely used technique in the writing process, which involved group discussions or mind mapping and listing ideas to generate many different thoughts and solutions. However, the method limits the search space, decreasing the diversity of ideas (Oanh, 2023). Thus, ChatGPT has become a potential tool to facilitate brainstorming and identification of relevant reference materials during the research process (Mutiara et al.,

2024). Furthermore, ChatGPT can help suggest article titles, expand or shorten articles, and even suggest creative ideas to improve the quality of articles (Zebua & Katemba, 2024).

Of course, AI tools may help thanks to Computer Mediated Communication (CMC). Language learners can communicate directly, inexpensively, and conveniently with other learners or speakers of the target language 24 hours a day, from school, work, or home. This communication can be asynchronous (not simultaneous) through tools such as electronic mail (email), which allows each participant to compose messages at their time and pace, or in can be synchronous ("real time"), which allow people all around the world to have a simultaneous conversation by typing at their keyboards. It also allows not only one-to-one communication, but also one-to-many, allowing a teacher or student to share a message with a small group, the whole class, a partner class, or an international discussion list of hundreds or thousands of people (Warschauer, 1996).

Advocates of the use of various kinds of technology-enhanced instruction have pointed to studies which suggest that students enjoy learning under such conditions, and find it less pressuring than traditional teaching, leading to an improved attitude towards the language-learning task. A fair amount of research has shown that a good experience of and/or success in learning a particular language can bring about favourable attitudes (Cook & Singleton, 2014).

2.2.2. Disadvantages and problems with AI Tools

According to Dziak (2024), some people believe that technology takes jobs away from human workers. Other people have resisted new technology because of its high cost, which may represent a major and risky investment for individuals and small businesses. Still, other people have avoided technology because it can be difficult to implement and learn how to use properly.

Chatbots are synchronous tools that support individual learning, however, pointed out that the limitation of technology itself (e.g, low accuracy of chatbots' responses) may diminish the degree to which chatbots can help improve students' performance. (Huang, Hew, & Fryer, 2022).

ChatGPT's feedback accuracy was found to be low, with wording that was often generic, abstract, and thus lacking concrete guidance for improvement. The authors suggested ChatGPT's analyses gave too much weight to the use of transitional words without being able to distinguish between effective and ineffective use of such words (Godwin-Jones, O'Neill & Ranalli, 2024).

It is precisely the abundant availability of not only information, but also misinformation and disinformation, which, if included in the data corpus that ChatGPT has been trained on, may lead to false information in its output. Thus, the possibility that ChatGPT can provide false information will require educators to include a strong focus on critical evaluative skills (Kostka & Toncelli, 2023).

Some uses of AI products in SLA have generally been seen positively (such as Automatic Writing Evaluation), the use of others has been controversial, with some language teachers, for example, attempting to ban student use of machine translation (Godwin-Jones, O'Neill & Ranalli, 2024).

Let's talk about contextual adaptation. In terms of contextual and cultural nuances. Culture provides the necessary context for accurate translation. It enables professional language translators to make informed decisions regarding word choices, tone, and style that align with the cultural expectations of the target audience (Ccelingo, 2023). However, students

do not always remember this element. In recent years, advancements in machine translation technology, such as Google Translate, and AI have made significant strides in facilitating cross-linguistic communication. However, these tools often struggle to capture the emotional subtleties and nuances inherent in human language (Najimova, 2024).

3.1. Methodology

3.1. Research Design

Since the purpose of the study was to explore the students' perspectives and engagement levels with AI Tools in Second Language Acquisition (SLA) Courses and to get more recommendations accordingly, this study employs a questionnaire as a cross-sectional survey to provide a comprehensive understanding of student engagement with AI in the subject SLA. The questionnaire was used to quantify students' attitudes and perceptions of AI usefulness, specific engagement behaviors (Quantitative) and to learn more about students' recommendations (Qualitative). This approach hopefully ensures an expectedly good assessment of how AI integration affects linguistic proficiency and overall learning outcomes.

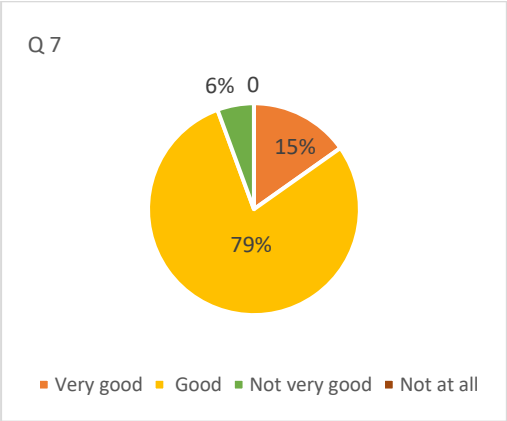
3.2. Description of Subjects

The participants of this research are 125 first-year students from the Faculty of Foreign Languages at HUFLIT University. These participants have specifically completed their Second Language Acquisition (SLA) courses, ensuring they possess the necessary direct experience with AI tool integration to provide informed perspectives on engagement and learning outcomes.

3.3. Instrument

It is a questionnaire form that consisted of 14 questions where likert-scales were used. 12 selected-response questions (close-ended questions) served as a quantitative measure, and 02 constructed-response questions (open-ended questions - Q6 and Q14) served as a qualitative measure to learn more about recommendations made by the students as survey participants.

3.4. Procedure



First, a questionnaire was cteated. Next, the forms were distributed to the two classes at the end of the course, namely, the last session. The students, as the survey participants, were allowed to spend 15 minutes completing the forms without providing their personal information. This is to ensure that they may feel free to contribute their points into the topic. The feedback of the respondents was colledted accordingly. After the data collection, the statistics were demonstrated and processed through MS Excel for information management and interpretation.

4. Findings

4.1. Digital Literacy and AI Readiness

This study addresses three primary research questions aligned with the stated objectives. However, the responses to Q7 "How would you rate your proficiency in using AI tools?" revealed the proficiency of the students, which was the baseline for the three others.

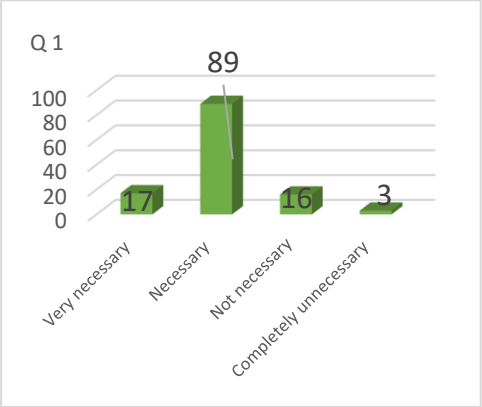


Fig.1 - Proficiency in using AI tools/ Apps

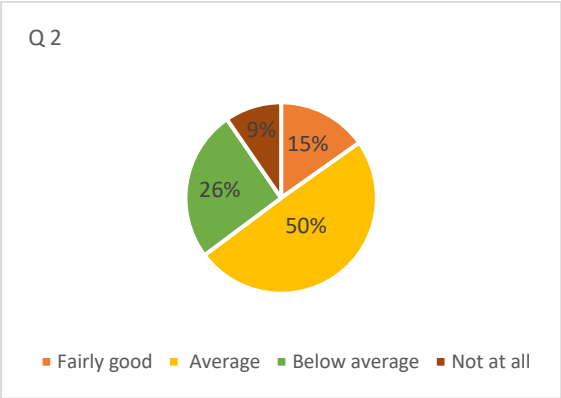
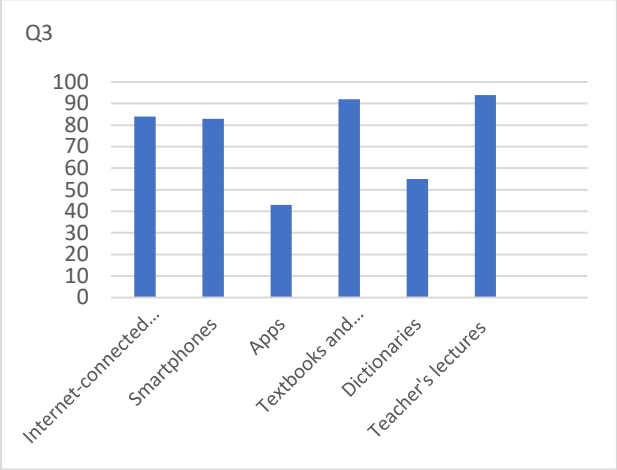
A significant majority of participants (94%) reported high proficiency in AI usage, with 15% rating themselves as "Very Good" and 79% as "Good". That claim shows the "HUFLIT English majors" in the study appear to be "high perceived digital self-efficacy" who are highly confident in their tech skills.



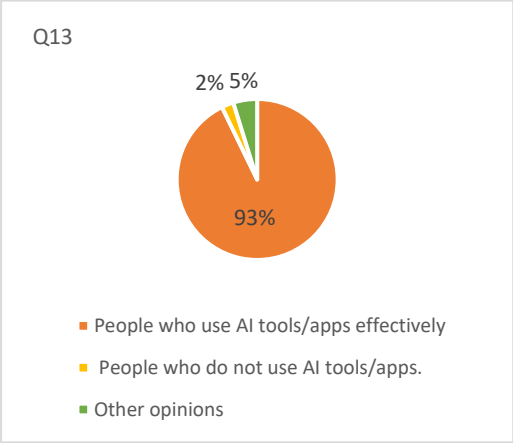
4.2. Perceptions of SLA & AI Necessity (Q1, Q2, Q13)

Fig.2 - The necessity of SLA



A majority (84%) confirmed the necessity of the subject SLA, with 13% rating as "Very necessary" and 71% as "Necessary". 15% thought that SLA is not. (16 responses indicating "not necessary" and 03 claiming "completely unnecessary")

Fig.3 - The level of understanding of the core knowlegde in SLA.



65% confirmed their understanding of the lessons (with 15% confirming "fairly good" and 50% as "average"). 35% of respondents said their understanding is not as good as expected (with 26% under average level and 09% with no understanding at all).

Fig.4 - Factors helping students' motivation in SLA

84 responses said that one of the factors helping students'motivation is using Internet-connected devices (accounting for 67,2%). Similarly, 83 respondents calimed that smartphones are another helping factor (accounting for 66,4%). However, the number indicating the teachers' lectures as a helping factor is 94 (accounting for 75,2%).

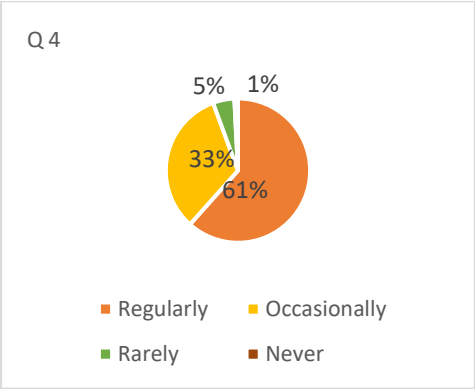


Fig.5 - Perceived learning advantages of AI tool users

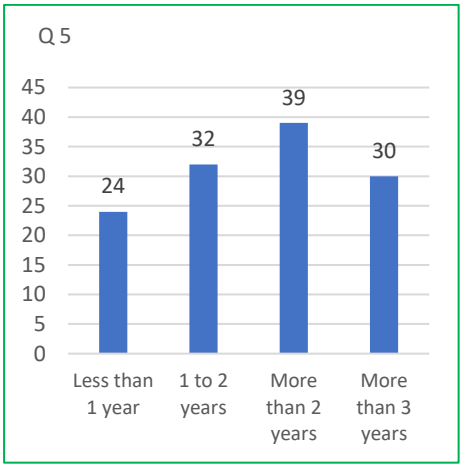
93% believed that with AI knowledge, learners may have an advantage in leraning. 07 % did not think so. While 93% students believe AI users have an advantage, only 84% see the subject itself as "Very Necessary" - suggesting a gap between tool utility and subject interest.



4.3. Patterns of AI Integration (Q4, Q5, Q6, Q8, Q9)

Fig.6 - Frequency of consulting AI Tools/ AI Apps for SLA

61% said that they regularly consulted AI Tools for the subject. 33 % - occasionally and 05% - rarely referring to AI.

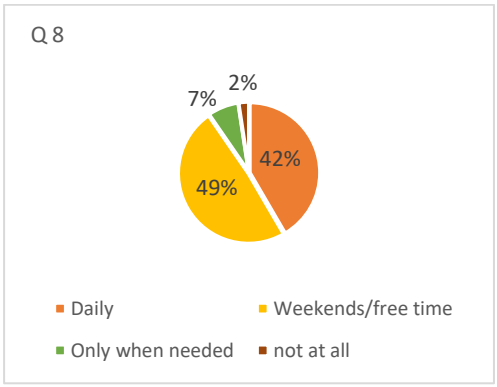


Fig.7 - Respondents' history with AI in education

19% stated that they have known GenAI for less than 1 year. 81% claimed that they have known AI tools for more than one year.

Q6 - When students were asked to list the names of the AI tools that they use for the SLA subject, they affirmed the "Big Three" tools (ChatGPT, Gemini, Google AI) and understandably, they indicated the reason why they use them: primarily for vocabulary and assignment support (See Q9).

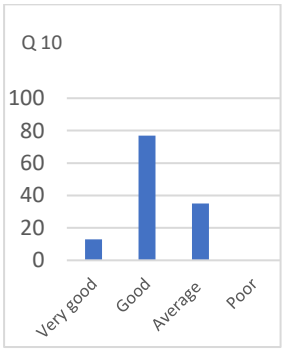

Fig.8 - Time refering to AI tools for SLA

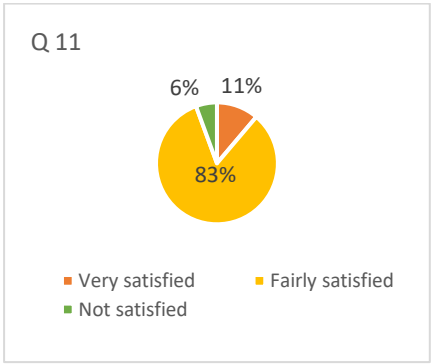
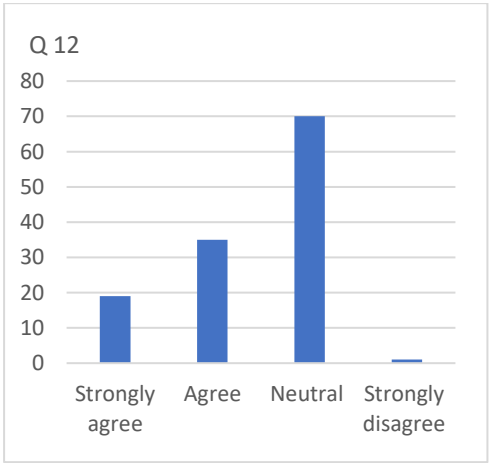
42% said that they referred to AI tools daily. 49% said that they referred to AI tools at weekends and in their free time. Only 02% confirmed that they did not refer to AI tools for the subject at all.



4.4. Satisfaction and Impact (Q10, Q11, Q12)

Fig.9 - Rating the responses by AI Tools



72% claimed that AI responses were good (with 10% - very good. 62% stated that AI feedback was good enough). 28% claimed it was average. No respondents claimed that AI feedback was poor.

Fig.10 - Satisfaction referring to AI Tools

94% felt happy with AI references (with 11% - extremely satisfied and 83% - fairly satisfied). Only 6% of the respondents claimed “not satisfied”.

Fig.11 - Levels of improvement when using AI Tools/ Apps

43% of them said that they have impvoved their learning when referring to AI tools (with 15% "strongly aggre" and 28% "agree"). 70 students accounting for 56 % stayed "neutral".

4.5. Findings of Q14 (Qualitative measure)

Themes	Initial Codes	Key Quotes by respondents as learners
Pedagogy & Instruction	Practice, tips, theoretical balance	"Theory needs to be applied to practice", "provide some tips for better understanding".
Curriculum Design	Challenge, compatibility	"SLA course material is truly challenging for first-year students".
Material Quality	Academic terms, lenghthy textbooks	"Textbook is too long and wordy", "many academic terms that are difficult to grasp".
AI Integration	AI overuse, critical thinking	"Reduce the overuse of AI to develop students' thinking skills".

5. Discussion

5.1. Quantitative Analysis (Q1 - Q13)

5.1.1. The "Utility vs. Value" Paradox

The "Utility vs. Value" paradox reveals a significant gap: while 93% of students acknowledge AI's competitive advantage, only 84% view Second Language Acquisition (SLA) as a necessary subject. This discrepancy suggests that many learners treat AI as a "shortcut" to bypass the cognitive struggle required to master complex theories. Instead of employing AI as a cognitive tool to deepen their understanding, students may rely on it as a compensatory tool simply to finish tasks faster. This trend risks prioritizing efficiency over genuine intellectual growth, potentially undermining the long-term internalisation of core SLA concepts.

5.1.2. The Performance-Learning Gap

The study reveals a critical "Performance-Learning Gap" - Students use it and they like the quality (Q10), but they aren't sure if it is making them "better" students yet. A standout contradiction in the data lies in the discrepancy between student satisfaction and perceived learning growth (Q11 vs. Q12). While a vast majority of respondents expressed satisfaction with the quality of AI-generated responses, over half (56%) remained "Neutral" regarding whether these tools significantly improved their actual mastery of Second Language Acquisition (SLA) core knowledge. This suggests a phenomenon that could be termed as "Illusion of Competence."

To be more specific, students may experience high user satisfaction because AI reduces the cognitive load required to complete immediate tasks, such as defining terminology or structuring assignments. However, this ease of task completion does not necessarily translate into deep cognitive processing. In the context of SLA, where internalizing complex theories require active mental struggle, the assistance provided by AI may be bypassing the very "desirable difficulties" essential for long-term retention. Consequently, without intentional pedagogical scaffolding to ensure AI tools promote active engagement rather than passive reliance, learners may achieve the desired end-product without developing the internal linguistic mental models required for long-term proficiency.

5.1.3. The Role of the Instructor in the AI Era

Recent findings highlight that 94% of students still view teachers' lectures as their primary motivator, significantly surpassing the influence of AI and smartphones. This underscores that even for "digitally skilled learners", the human element remains the core driver of academic engagement. Consequently, AI must be viewed strictly as a supplement rather than a replacement for professional guidance. Instructors play a vital role in interpreting complex SLA concepts, providing nuanced pedagogical insights and personal connections that technology cannot replicate effectively.

This survey aligns with Kostka & Toncelli 's points. It is undeniable that while ChatGPT offers many advantages, it is not a replacement for a qualified human teacher. Effective integration of ChatGPT into an English language classroom would require thoughtful planning and a blended approach, combining technology with human interaction, guidance, and feedback. A teacher's expertise in understanding individual student needs, offering encouragement, and fostering a supportive learning community is irreplaceable and would complement the benefits offered by ChatGPT (Kostka & Toncelli, 2023).

Although technologies may be powerful and advanced, they cannot function without human cooperation (Dziak, 2024). It has clearly been shown that teachers can promote and sustain higher motivation levels by helping learners to identify short-term goals and to reflect on their progress and achievements (Cook & Singleton, 2014).

5.1.4. Implications for Pedagogy and Curriculum Design

The findings of this study necessitate a shift in how SLA is taught within the English Department at HUFLIT. Since students demonstrate high digital literacy but uncertainty regarding AI's impact on their learning growth, the curriculum should move away from traditional "output-based" assignments that AI can easily replicate. Instead, the following implications should be considered. First, it is Integration of AI-Reflective Tasks: Rather than banning AI, lecturers should design tasks where students must use AI to generate an SLA analysis and then critically evaluate that analysis using core textbook theories. This forces the "Neutral" group to engage in the deep processing they feel are currently missing. Second, it is Assessment Reform: With 93% of students recognizing the "AI advantage", assessment should pivot toward in-class, process-oriented evaluations - such as the debate skills already emphasized in the curriculum - where the human element of spontaneous linguistic interaction remains central.

5.2. Qualitative Analysis (Q14)

Qualitative analysis of the open-ended responses reveals four primary themes concerning the enhancement of teaching and learning quality.

First, regarding pedagogical approaches, students emphasized the necessity of bridging the gap between theory and practice. Respondents noted that "theory needs to be applied to practice" and suggested an increase in practical contact hours.

Second, the curriculum - specifically the SLA course - was perceived as overly broad and theoretical, posing significant challenges for first-year students. Consequently, learners expressed a need for instructional tips and clearer guidance from instructors to facilitate better comprehension.

Third, the quality of learning materials was identified as a major pedagogical barrier. A majority of respondents characterized the current textbook as "too long and wordy", noting that it contains numerous "academic terms that are difficult to grasp". This suggests an urgent need to streamline content and adopt materials that are more accessible and tailored to the proficiency levels of novices and appropriateness.

Finally, a concern regarding technology integration emerged; participants recommended mitigating the overuse of AI to prioritize the development of students' independent thinking skills. These findings collectively underscore the requirement for a strategic realignment of both course materials and instructional methods to better suit the developmental needs of first-year students.

6. Conclusion

6.1. Evaluation

The survey clearly reflects students' perceptions and positive attitudes towards the subject, toward the integration of AI in SLA, predominant AI tools and usage patterns exhibited by these students in their language learning routines. In other words, it reveals the trend of students' strong engagement with digital technology, their openness but alertness when using digital tools, and full awareness of the necessary factors to improve the subject, especially the textbook as learning materials. These results are an important basis for improving the SLA curriculum and effectively combining traditional methods and modern technology in training.

6.2. Recommendations

6.2.1. Recommendations from survey respondents

Researchers have focused on how learners react to how they engage with the target language, including how they respond to the teacher's approach, to the learning materials to which they have access (Cook & Singleton, 2014). The feedback on question 14 showed the students' recommendations on the learning materials they had just learned, including three main points:

(1) Practicality: Theory needs to be applied to practice; more practical hours are needed.

(2) Content: What they had learned seemed too theoretical and difficult to grasp. The content should be streamlined to suit the learning needs of first-year students. The instructor needs to provide some tips for better understanding.

(3) SLA course material: It is truly challenging for first-year students; The textbook is too long and wordy. The textbook needs improvement; The material should be less dry, as it contains many academic terms that are difficult to grasp.

6.2.2. Recommendation from author

In the era of high-tech and AI, teachers must proactively develop AI literacy to avoid becoming outdated. Integrating these tools allows educators to personalize learning, automate

administrative tasks, and create engaging content. Proficiency in AI doesn't just simplify workloads; it empowers teachers to provide more effective, data-driven support, ensuring they remain relevant in a modern classroom. AI tools may help create interactive input in SLA.

6.3. Limitations

Although the study has achieved its goals, there are still some shortcomings. The study presents the inherent limitations of focusing on a specific learner group. In other words, the investigation was a minor study, and its findings were applied to only 2 classes of The Faculty of Foreign Languages of Ho Chi Minh University of Foreign Languages - Information Technology. Thus, it may generally not represent universities all over the country.

The survey was completed in a short amount of time. The students had roughly 15 minutes to complete the questions, which may influence their reflections. Due to the limited availability of time, only some factors were carefully analyzed, other facets maybe not be properly speculated.

6.4. Implications

These findings not only open up directions for further research but also provide a practical basis for educators to improve their curricula, effectively combining traditional methods and modern technology, in order to optimize the training process.

The students' responses reveal several significant implications regarding their attitudes, learning strategies, and expectations concerning the integration of AI in education, particularly for the SLA subject.

(1) Desire for Self-Reliance: Students value their own intellectual effort and want to avoid becoming passive recipients of AI-generated content, suggesting a motivation to develop their own skills rather than solely relying on external tools.

(2) Recognition of AI's Limitations and Strengths: Students understand that AI is a "suggestion, not a replacement".

(3) Proactive and Adaptable Mindset Towards Technology: Instead of resisting AI, students are open to embracing it. They see AI as an inevitable part of the future workforce and want to be equipped with the skills to use it effectively, aligning with development trends.

(4) Curriculum Redesign: Move away from "wordy" textbooks toward more interactive, AI-assisted practical workshops.

(5) Critical AI Literacy: A framework for "Guided AI Use" should be set up where the instructor sets boundaries on when to use ChatGPT versus when to use human critical thinking. Students need to learn how to appropriately and ethically incorporate AI-generated content into their own work (Tseng & Warschauer, 2023).

AI cannot ever replace us in these essential aspects of our work as educators, yet it might make our work more interesting, engaging, and innovative (Kostka & Toncelli, 2023).

Bio:

She earned her M.A in Applied Linguistics from La Trobe University Australia. She has over 30 years of English teaching experience at university level. Her first job was working at The Office of International Affairs, HCM University of Technology as an interpreter and translator. Her second job was teaching ESP at HCM University of Technology. Then she has so far worked at Huflit as a lecturer in Faculty of Foreign Languages. Her interest includes teaching English Linguistics and ESP. As an educator, she welcomes AI integration, but she absolutely appreciates the combination between traditional teaching approach and new ones.

Appendix

SURVEY QUESTIONNAIRE

Question 1: Do you think the subject of Second Language Acquisition (SLA) is necessary for your curriculum?

a) Very necessary

b) Necessary

c) Not necessary

d) Completely unnecessary

Question 2: How would you rate your understanding of the core knowledge of SLA?

a) Fairly good

b) Average

c) Below average

d) Not at all

Question 3: In your opinion, which of the following factors help students be more motivated to study SLA? *(You may choose multiple options)*

a) Internet-connected devices (computer, laptop, iPad, etc.)

b) Smartphones

c) Application software (Apps)

d) Textbooks and reference books

e) Various types of dictionaries

f) Teacher's lectures in class

g) Other:

_____

Question 4: When you need to understand the core knowledge of SLA, do you often consult AI/AI Apps? (e.g., ChatGPT, Gemini, Google AI, Online Dictionary, etc.)

a) Regularly

b) Occasionally

c) Rarely

d) Never

Question 5: Since when have you known about AI tools and its applications in education?

a) Less than 1 year

b) 1 to 2 years

c) More than 2 years

d) More than 3 years

Question 6: Could you please list the AI tools/apps that you use for the SLA subject?

_____

_

Question 7: How would you rate your proficiency in using AI tools/apps?

a) Very good

b) Good

c) Not very good

d) Not at all

Question 8: How much time do you spend using AI tools for this subject?

a) Daily

b) Weekends or free time

c) Only when needed

d) No time spent on AI tools

Question 9: For what purposes do you use AI and Apps when studying SLA?*(You may choose multiple options)*

a) Checking vocabulary and terminologeies of the subject

b) Generating ideas for class assignments

c) Supporting assignments on Moodle

d) Checking answers to exercises

e) Focusing on core lessons

f) Other purposes: _____

Question 10: How would you rate the responses provided by these AI tools/apps?

a) Very good

b) Good

c) Average

d) Poor

Question 11: Are you satisfied with the suggestions provided by AI tools/apps for this subject?

a) Very satisfied

b) Fairly satisfie

c) Not satisfied

Question 12: In your opinion, your learning has improved significantly when using AI tools/**apps?**

a) Strongly agree

b) Agree

c) Neutral

d) Disagree

e) strongly disagree

Question 13: Which group of people do you think has an advantage in learning?

a) People who use AI tools/apps effectively

b) People who do not use AI tools/apps

c) Other opinions:

_____

Question 14: Please provide any suggestions you have for the SLA course.

_____

_

Thank you very much for participating in this survey.

#49 Developing Intercultural Pragmatic Competence for Real Life Interaction through Role-Play: Teaching the Speech Act of Requests in Vietnamese English Communication Classes in the Transition from EFL-Oriented to ESL-Oriented Pedagogy

Nguyen Hoang Vuong Anh, Nguyen Tan Khoa

Abstract

In recent years, English education in Vietnam has increasingly emphasized communicative competence and the use of English for interaction as the country shifts toward a more ESL-oriented context. However, classroom instruction still largely prioritizes grammatical knowledge and linguistic accuracy over pragmatic aspects of communication. Within communicative competence, the ability to perform speech acts appropriately is essential, as effective interaction requires sensitivity to social context, power relations, and cultural norms. Among speech acts, requests are particularly important due to their variability across languages and their role in managing interpersonal relationships. Despite this significance, instructional approaches to teaching requests remain underexplored in Vietnam.

This study examines how role-play activities can be used to teach the speech act of requests in Vietnamese English communication classes and how they support the development of students' intercultural pragmatic competence. Adopting a classroom-based case study design, the research involved 41 freshmen enrolled in an English communication course at the Faculty of Foreign Languages, HUFLIT University. Data were collected through classroom observations, recordings of role-play interactions, and students' task performances, and were analyzed using pragmatic discourse analysis.

The findings show that role-play enhances students' ability to perform the speech act of requests appropriately across diverse social contexts and provides empirical evidence for integrating pragmatic, interaction-based instruction. These results highlight the significance of role-play as a pedagogically effective approach in facilitating the transition from grammar-focused EFL practices to a more communicative, socially grounded ESL-oriented approach in Vietnam.

***Keywords*:** intercultural pragmatic competence, role-play, speech acts (requests), ESL-oriented pedagogy

1. Introduction

Effective English communication involves both grammatical accuracy and contextually appropriate language use. This ability, known as pragmatic competence, is especially important when learners move from EFL to ESL settings, where communication occurs more frequently in real-life situations.

In university contexts, students often need to perform tasks such as emailing lecturers, asking for clarification, or requesting assistance. These interactions require an understanding of politeness and social relationships. Nevertheless, classroom practices in many Vietnamese EFL settings continue to prioritize linguistic forms and vocabulary development, leaving relatively little room for the systematic development of pragmatic abilities.

Previous studies have examined learners' request strategies and highlighted the effectiveness of role-play activities in developing pragmatic competence and intercultural awareness. However, little research has explored how interaction-based role-play activities help students improve the pragmatic appropriateness of requests, develop request strategies and mitigating devices, and facilitate the shift from grammar-focused EFL instruction to communicative ESL-oriented learning.

Therefore, further research is needed to explore how role-play activities contribute to developing intercultural pragmatic competence among Vietnamese university students.

To address this issue, the study examines how interaction-based role-play activities facilitate students' use of the speech act of requests and the development of intercultural pragmatic competence. Specifically, it examines the pedagogical implementation and analyzes how these activities facilitate students' transition toward an ESL-oriented communicative approach. To guide this investigation, the following research questions are proposed:

(1) To what extent does the integration of role-play activities improve students' pragmatic appropriateness in performing the speech act of requests?

(2) How do students develop request strategies and use of mitigating devices during role-play activities?

(3) How do students perceive the role of role-play in supporting the shift toward more ESL-oriented communicative practices?

The study first outlines key concepts related to interlanguage pragmatics and intercultural competence. The next section presents the research design, participants, and data collection process. The findings are subsequently presented and analyzed, followed by a discussion of pedagogical implications. The final section summarizes the findings and offers recommendations for future research.

2. Literature Review

2.1 Pragmatic Competence in Interlanguage and Intercultural Pragmatics

2.1.1. Pragmatic Competence

Pragmatic competence is a key aspect of communicative competence. According to Hymes, D. (1972), successful communication depends on both linguistic knowledge and appropriate language use. Based on this idea, Canale, M., & Swain, M. (1980) regarded sociolinguistic competence as an essential element of communicative competence. Later, pragmatic competence was further described as a fundamental component of language proficiency that combines knowledge of language forms with an understanding of social and cultural contexts (Bachman, L. F.,1990). Collectively, these perspectives indicate that effective communication requires a combination of linguistic resources and context-sensitive language use.

More specifically, researchers commonly describe pragmatic competence as the capacity to select and employ language forms that are appropriate for a given communicative situation. According to Leech, G. N. (1983) and Thomas, J. (1983), successful language use depends on selecting language that fits the communicative context. Pragmatic competence combines language knowledge with an understanding of social and cultural expectations. (Kasper, G., & Rose, K. R., 2002). As a result, communication problems may arise when learners focus on grammar without considering social and contextual appropriateness. (Blum-Kulka, S. et al., 1989).

Pragmatic competence is also closely related to culture. The same expression can have different meanings in different cultural and social contexts, which may lead to misunderstanding (Ishihara, N., & Cohen, A. D., 2010). Thomas, J. (1983) argued that communication problems often result from pragmatic failure rather than grammatical errors. For this reason, teaching pragmatics should go beyond language forms and help learners develop intercultural awareness. This can enable them to communicate more effectively and appropriately in different situations.

2.1.2 Interlanguage Pragmatics

Interlanguage pragmatics investigates learners' acquisition and use of pragmatic knowledge. Kasper, G., & Schmidt, R. (1996) define the field as the study of learners' acquisition and use of language in socially appropriate ways. According to Kasper, G., & Rose, K. R. (2002), interlanguage pragmatics explores how learners develop pragmatic competence and apply it in various communicative situations. Similarly, Bardovi-Harlig, K. (2013) argues that learners are required to adapt their language to various communicative contexts..

A substantial body of interlanguage pragmatics research has investigated speech acts including requests, apologies, and refusals, as well as the teaching and assessment of pragmatic competence (Rose, K. R., 2005 & Taguchi, N., 2015). Despite this growing body of research, interactional competence has received less attention, even though it plays a central role in successful communication (Taguchi, N., & Roever, C., 2017). Learners who lack sociopragmatic awareness may have difficulty interpreting social norms and cultural expectations, which can lead to misunderstandings in intercultural interactions. Such difficulties indicate that learners may benefit from explicit pragmatics instruction.

2.1.3 Intercultural Pragmatics

Intercultural pragmatics examines how cultural knowledge and experience shape cross-cultural communication. Kecskés, I. (2014, 2016) explains that people from different cultures may interpret and use language in different ways during communication. McConachy, T. (2022) further argues that learners' understanding and production of meaning are shaped by their previous experiences and cultural knowledge. As a result, speakers often need to negotiate meaning and build common ground to achieve successful communication.

Pragmatic meanings are also influenced by cultural views of politeness, power, and social relationships rather than being universally shared (Spencer-Oatey, H., 2008; Kádár, D. Z., & Haugh, M., 2013). For this reason, intercultural communication requires flexibility and the ability to mediate between different perspectives. Liddicoat, A. J. (2022) emphasizes the importance of intercultural mediation, while Byram, M. (2011) and McConachy,T. (2018) describe language learners as intercultural speakers who adapt their language use to different contexts instead of simply copying native-speaker norms. These perspectives highlight the need to develop both pragmatic competence and intercultural awareness in language education.

2.2 Requests as Speech Acts in Pragmatics

Requests are important speech acts because they may pressure the listener and threaten their social image (Ellis, R., 2003). Therefore, producing requests requires careful attention to contextual variables such as power relations, social distance, and degree of imposition. In addition, speakers must select appropriate strategies that vary in terms of directness and politeness.

Furthermore, research on request perception shows that indirect requests are highly context-dependent. In particular, Taguchi, N. (2015) demonstrate that hearers rely heavily on

contextual cues to interpret intended meaning. Moreover, advanced learners may develop native-like perceptions of politeness, although their judgments are still influenced by instruction and learning experience (Taguchi, N., & Roever, C., 2017).

In addition, research suggests that request strategies vary across cultures because of different sociocultural expectations (Ogiermann, E., 2009 & Dong, X., 2009). As a result, learners with greater exposure to the target language and authentic interaction are generally more capable of producing contextually appropriate requests (Han, S., 2005).

2.3 Learners' Pragmatic Performance in Using Requests

Braj B. Kachru's three-circle model classifies countries according to the role of English as an inner-circle, outer-circle, or expanding-circle language (Kachru, B. B., 1982 & Crystal, D., 2003). In this regard, the distinction is important because learning environments strongly influence pragmatic development.

Specifically, learners in ESL contexts are exposed to authentic communication and therefore tend to develop more contextually appropriate request strategies (Bardovi-Harlig, K. & Dörnyei, Z., 1998 & Schauer, G. A., 2006). In contrast, EFL learners often have limited opportunities for real-life interaction and depend more heavily on classroom input. As a result, they are more likely to experience stronger L1 influence and less appropriate request performance (Ishihara, N., & Cohen, A. D., 2010).

Furthermore, Austin's Speech Act Theory provides an important framework for studying requests. According to Austin, J. L. (1962), language is used not only to convey information but also to perform actions such as requesting or apologizing. Building on this idea, Searle, J. R. (1979) further distinguishes between direct and indirect speech acts, emphasizing that indirect requests are often preferred because they reduce imposition and maintain politeness. Similarly, Brown, P., & Levinson, S. C. (1987) highlight the importance of indirectness in English-speaking contexts.

In addition, cross-cultural studies compare request strategies across languages and cultures, thereby revealing differences in directness and politeness (Blum-Kulka, S., et al., 1989). By contrast, interlanguage studies focus on how learners acquire and use request strategies in a second language while considering factors such as proficiency, learning environment, and L1 influence (Kasper, G., & Dahl, M., 1991).

2.4 Pragmatics Instruction: Theoretical and Empirical Perspectives

Research on pragmatic instruction is generally informed by both cognitive and sociocultural perspectives. From the cognitive perspective, DeKeyser, R. M. (2007) emphasize the roles of noticing, attention, and explicit instruction in developing pragmatic awareness. In contrast, from the sociocultural perspective, Vygotsky, L. S. (1978) stress the importance of interaction and collaborative meaning-making in language learning.

More recently, these perspectives have been viewed as complementary rather than contradictory. In particular, explicit instruction helps raise learners' metapragmatic awareness, whereas interaction promotes practice and the automatization of pragmatic knowledge (Ishihara, N., 2010 & Taguchi, N., 2015).

Furthermore, empirical studies support the effectiveness of explicit instructional techniques such as metapragmatic explanation and role-play in improving learners' use of request strategies (Takahashi, S., 2010). At the same time, authentic input and interaction play an important role in developing sociocultural understanding and communicative fluency

(Taguchi, N., 2015). However, limited exposure to authentic communication in EFL settings may hinder pragmatic development (Kasper, G., & Rose, K. R., 2002). Therefore, combining explicit instruction with interaction-based activities is widely considered an effective approach to teaching pragmatics.

3. Methodology

3.1 Research Setting

This research was carried out at the Faculty of Foreign Languages, HUFLIT, a private university in southern Vietnam.

The research took place in an English communication course for first-year students, which is a compulsory subject aimed at enhancing learners' speaking and interactional skills in real-life contexts. The course focuses on developing students' ability to use English effectively in everyday communication, incorporating interactive teaching methods such as role-play, group discussions, and situational simulations. In particular, role-play activities are regularly employed to simulate authentic communicative situations, allowing students to practice language functions such as making requests, giving suggestions, and expressing opinions.

The course is typically organized into weekly sessions that combine both theoretical input and practical activities. These activities are designed not only to improve linguistic competence but also to raise students' awareness of sociocultural norms and pragmatic conventions in English communication.

3.2 Participants

The study involved 41 first-year students in an English communication course. Convenience sampling was used, with participants selected based on availability at HUFLIT. Although the study was conducted in a single institutional context, the classroom reflected common characteristics of Vietnamese EFL communication classes that are increasingly incorporating ESL-oriented communicative practices.

3.3 Research Instruments

To examine students' use of request strategies and the development of intercultural pragmatic competence, this study adopted a mixed-methods approach, employing multiple instruments: a Written Discourse Completion Task (WDCT), a questionnaire, role-play tasks, and classroom observations. Employing multiple sources of evidence strengthened the trustworthiness and credibility of the research outcomes.

The WDCT was used to elicit written request strategies across six scenarios reflecting variations in power, distance, and imposition (Brown, P., & Levinson, S. C., (1987). A questionnaire (25 items) investigated students' perceptions of role-play and pragmatic development, combining Likert-scale items (e.g., pedagogical effectiveness, pragmatic competence, intercultural awareness, psychological factors) and multiple-choice questions on communicative behavior and L1 influence.

Role-play tasks served as the primary source of spoken data, requiring students to perform requests in interactive contexts based on similar sociopragmatic variables. Their interactions were audio-recorded for analysis. In addition, classroom observations were conducted to capture students' engagement and interaction patterns, supported by field notes.

3.4 Procedure

Data were collected during regular English communication classes through multiple complementary stages. First, a WDCT with six scenarios was administered online to elicit written request strategies in controlled contexts, providing baseline data.

Second, role-play activities were implemented to simulate real-life interactions. Students performed in pairs or groups, and their interactions were audio-recorded to capture authentic spoken data. Classroom observations were conducted concurrently, with field notes documenting engagement and interaction patterns.

Finally, a 25-item questionnaire was administered to gather students' perceptions of role-play and its contribution to their intercultural pragmatic development. Responses were collected anonymously to ensure reliability.

Overall, the use of multiple data sources such as written (WDCT), spoken (role-play), observational, and self-reported enabled triangulation and a comparative analysis of students' pragmatic performance across task types.

3.5 Data Analysis

Data from multiple instruments were analyzed using both qualitative and quantitative approaches to examine students' use of request strategies and their intercultural pragmatic competence. First, the WDCT responses were exported to Excel and coded deductively based on Blum-Kulka and Olshtain's framework, focusing on levels of directness and politeness features; subsequently, the data were quantified to identify patterns across contexts. Next, role-play recordings were transcribed and analyzed using pragmatic discourse analysis to examine strategy use, directness, and contextual appropriateness in real-time interaction. Meanwhile, questionnaire data were analyzed quantitatively, with Likert-scale items calculated in terms of frequencies, percentages, and mean scores, and multiple-choice items examined descriptively to identify trends in learners' perceptions and strategy use. In addition, classroom observation notes were analyzed qualitatively to provide supporting evidence and triangulate the findings.

Overall, the integration of multiple data sources enhanced the validity and reliability of the study.

4. Results

4.1. Vietnamese EFL Learners' Realization of Speech Act of Requests: Findings from the WDCT

The quantitative analysis of the WDCT provides a comprehensive baseline of the participants' pragmatic competence. The data were categorized based on the directness levels and specific request strategies following the Cross-Cultural Study of Speech Act Realization Patterns (CCSARP) framework.

4.1.1. Overall Distribution of Request Directness

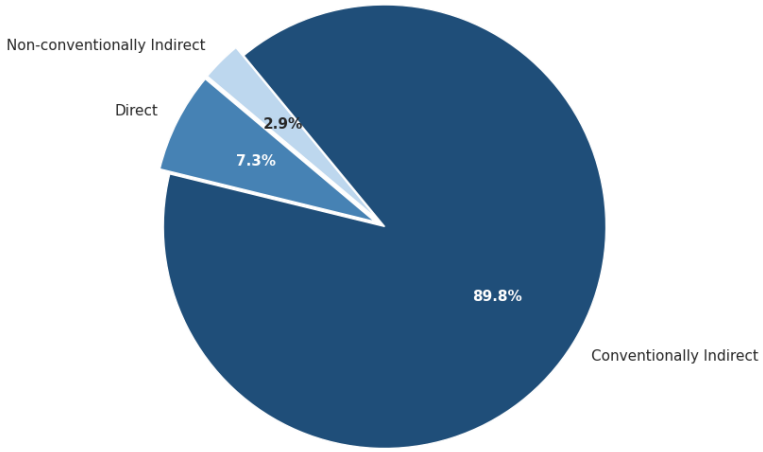

Figure 1. *Distribution of Request Directness in WDCT (N=41)*

As presented in Figure 1, the participants demonstrated a clear preference for Conventionally Indirect strategies, which accounted for the vast majority of the total requests (89.8%). In contrast, Direct strategies were used far less frequently (7.3%), while Non-conventionally Indirect strategies (Hints) were the least frequently employed (2.9%). The results indicate that participants generally recognized the importance of politeness and indirectness when making requests in English. However, the overwhelming reliance on conventionally indirect forms also indicates a tendency toward formulaic language use, with limited variation in pragmatic strategy selection across contexts. While the learners appeared capable of producing pragmatically acceptable requests in many situations, the findings also suggest that their pragmatic repertoire remained relatively restricted.

4.1.2. Situational Variation in Request Strategies

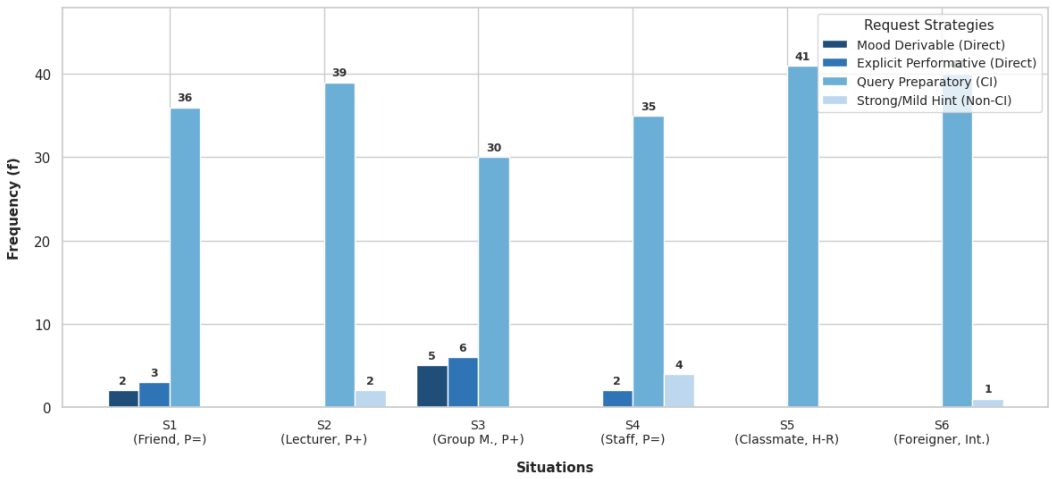

Figure 2. *Distribution of Request Strategies across Six Situations (N=41)*

Figure 2 demonstrates that the Query Preparatory strategy was the most dominant across all six scenarios, maintaining a near-absolute presence in Situations 5 and 6 (100% and 98% respectively). This indicates that when faced with high imposition (S5) or intercultural contexts (S6), learners almost exclusively resort to safe, conventionalized questions about ability or willingness (e.g., "Can you...").

However, a notable deviation in directness levels was observed in Situation 3 (Group Leader to Member, P+), where Direct strategies (Mood Derivable and Explicit Performative) reached their highest frequency at 27%. This shift suggests that learners are sensitive to the Power (P) variable; they tend to adopt a more authoritative and blunt tone when they perceive themselves in a superior social position.

In contrast, Situation 2 (Lecturer, P+) and Situation 4 (Staff, D+) elicited the most consistent use of polite, indirect formulas. Interestingly, while Non-conventionally Indirect strategies (Hints) remained the least used overall, they appeared more frequently in Situation 4 (10%), as learners attempted to use subtle remarks to address a stranger in a service context.

Overall, the data in Table 2 reinforces the finding that while Vietnamese EFL learners at HUFLIT attempt to calibrate their requests according to social variables like Power and Distance, their pragmatic repertoire remains constrained. They rely heavily on a "one-size-fits-all" indirectness for most scenarios, only occasionally venturing into direct commands when the social hierarchy permits.

4.2. Vietnamese EFL Learners' Pragmatic Performance in Real-Time Interaction: Findings from the Role-Play Recordings

4.2.1. Patterns of Pragmatic Performance in Role-Play Interaction

Analysis of four role-play recordings revealed a consistent pattern in students' pragmatic performance during real-time interaction. Overall, the findings indicate that while students demonstrated awareness of polite request strategies in written tasks, they experienced notable difficulty maintaining such politeness when engaged in spontaneous spoken communication.

One prominent trend was a shift from indirect to more direct request strategies. In WDCT, students typically produced longer and more mitigated forms, such as "I wonder if you could help me…". However, in the recordings, these were frequently replaced by shorter and more direct expressions, including "Give me" or "Can I borrow". This shift suggests that under time pressure, students prioritized efficiency and immediate comprehensibility over pragmatic appropriateness.

4.2.2. Key Challenges in Real-Time Request Production

The analysis also revealed evidence of first language (L1) pragmatic transfer. In several instances, students appeared to rely on Vietnamese syntactic and pragmatic patterns when formulating requests in English. For example, the utterance "Give me your notebook" reflects a direct translation of a common Vietnamese request form ("Cho mình mượn"), without the use of mitigating devices typically expected in English. Although not intended to be impolite, such forms may be perceived as abrupt in English-speaking contexts.

In addition, the recordings showed clear signs of processing difficulty. Across all four interactions, students frequently produced hesitation markers such as "uhm" and "ah", along with pauses ranging from two to four seconds. These features suggest a cognitive load

associated with simultaneously managing lexical retrieval, grammatical encoding, and pragmatic decision-making during real-time speech production.

Finally, students demonstrated difficulty handling unexpected responses from their interlocutors. When faced with refusals or conditional replies (e.g., a partner indicating that they also needed the item), many students struggled to adapt their requests. Instead of employing supportive moves such as providing justification or negotiation (e.g., "I only need it for a moment" or "I'll return it immediately"), they often repeated their initial request or responded minimally without further elaboration.

In summary, the findings from the four role-play recordings suggest a gap between students' declarative knowledge of politeness strategies and their ability to apply this knowledge in real-time interaction. Under communicative pressure, their language use became more direct and was strongly influenced by L1 pragmatic norms.

4.3. Learners' Pragmatic Perception and Pedagogical Evaluation: Findings from the Questionnaire

4.3.1 Students' Perceptions toward Role-play Activities

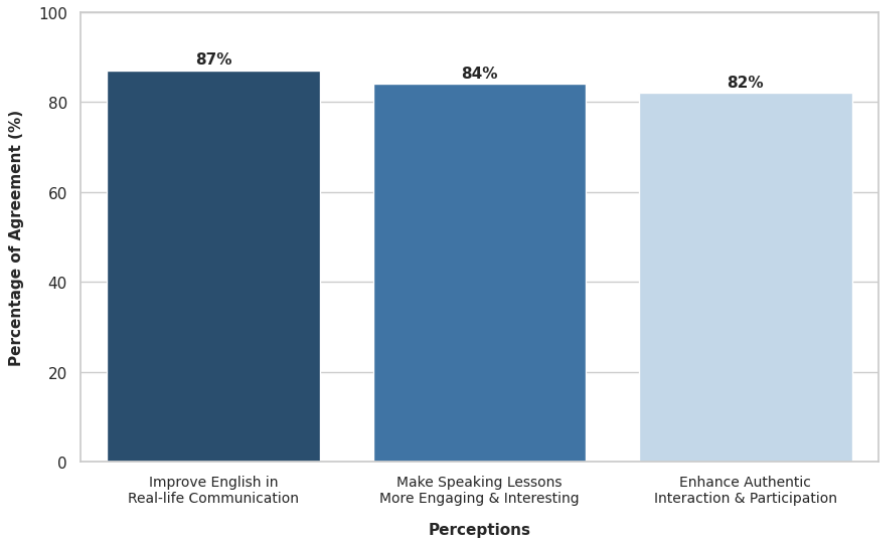

Figure 3. *Students'Perceptions toward Role-play Activities*

The questionnaire results revealed generally positive attitudes toward the use of role-play activities in English communication classes. Most participants agreed that role-play created a more engaging and interactive learning environment.

As illustrated in Figure 3, approximately 87% of the participants agreed that role-play activities improved their ability to use English in real-life communication, indicating that students perceived role-play as beneficial for communicative development. Similarly, around 84% of the respondents reported that role-play activities made speaking lessons more engaging and interesting. In addition, about 82% of the students believed that role-play activities enhanced authentic interaction and active classroom participation. These findings suggest that role-play was viewed as an effective communicative approach that facilitated meaningful language use in classroom contexts.

Overall, the findings demonstrated that students perceived role-play activities positively and considered them beneficial for improving classroom interaction, learner engagement, and English communication competence.

4.3.2 Role-play and Intercultural Pragmatic Development

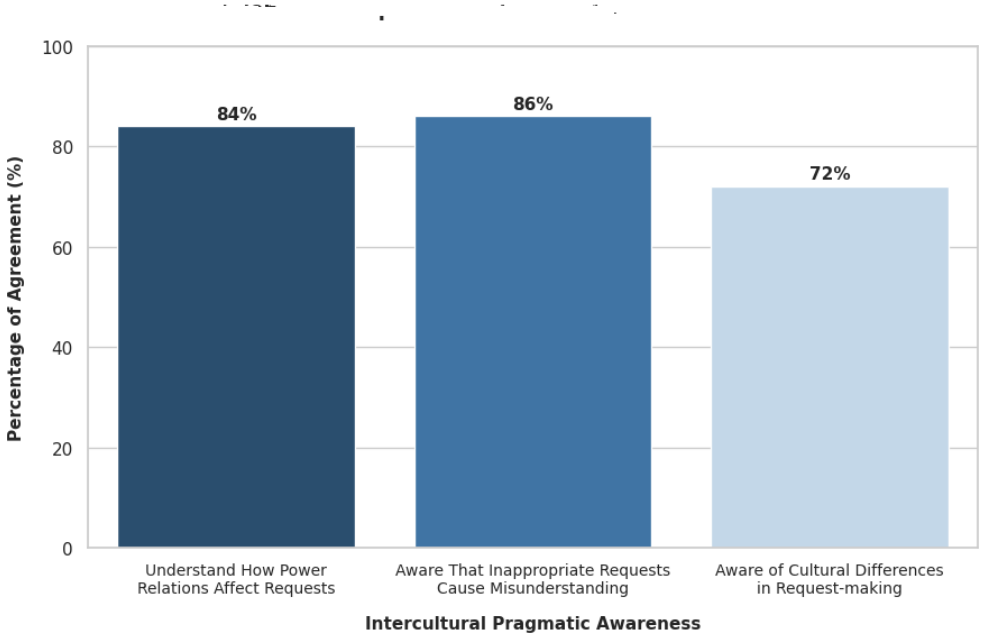

Figure 4. *Students' Perceptions toward Intecultural Pragmatic Development*

The findings revealed that role-play activities contributed positively to students' intercultural pragmatic development. Many participants demonstrated awareness of how social and cultural factors influence communication when making requests in English.

As shown in Figure 4, approximately 84% of the participants agreed that they understood how power relations affect requests, indicating that students recognized the importance of social status and hierarchy in communication. In addition, around 86% of the respondents reported awareness that inappropriate requests may cause misunderstanding in intercultural communication. Students also showed awareness of cultural differences in request-making although the level of agreement for this item was slightly lower, with approximately 72% of participants expressing positive responses. This finding suggests that while students had developed intercultural pragmatic awareness, additional exposure to authentic intercultural communication may still be necessary.

Overall, the findings indicate that role-play activities supported the development of intercultural pragmatic competence by helping students understand contextual appropriateness, politeness, and social relationships in English communication.

4.3.3 Pragmatic Awareness in Using Speech Acts of Request

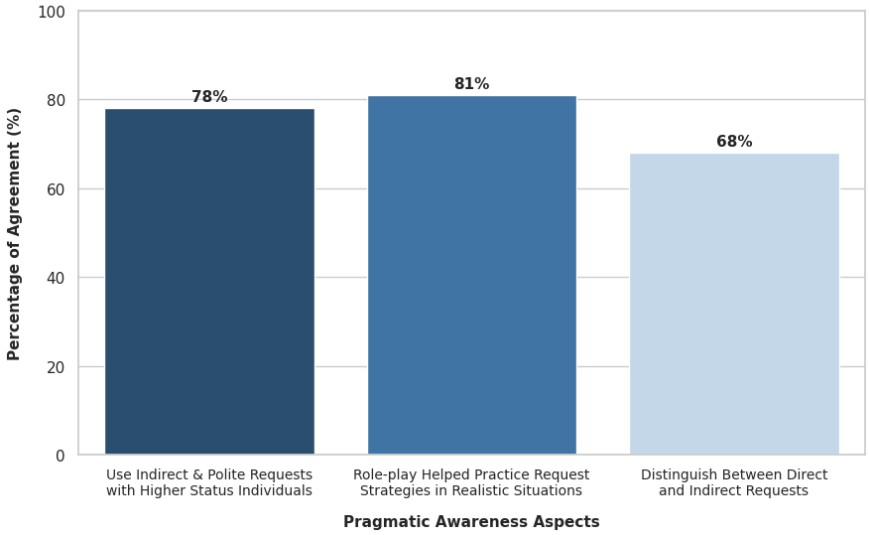

Figure 5. *Students' Pragmatic Awawreness in Using Speech Acts of Request*

The questionnaire results demonstrated that students developed a relatively strong awareness of pragmatic appropriateness when using speech acts of request.

Most participants agreed that requests should be adjusted depending on the context, social relationship, and level of politeness required in communication. As illustrated in Figure 5, approximately 78% of the respondents reported that they tended to use indirect and polite requests when communicating with someone of higher social status.

Additionally, around 81% of the participants indicated that classroom role-play activities helped them practice request strategies in realistic situations. Many respondents also stated that teachers frequently provided feedback regarding the appropriateness and cultural use of requests during classroom interaction. However, the item related to distinguishing between direct and indirect requests received a comparatively lower level of agreement, with approximately 68% of students expressing positive responses. This finding suggests that although students demonstrated general pragmatic awareness, some still experienced difficulty identifying and applying different request strategies accurately.

Overall, the findings suggest that role-play activities positively influenced students' pragmatic awareness and their ability to use speech acts of request more appropriately in English communication.

4.3.4 Emotional and Communicative Effects of Role-play Activities

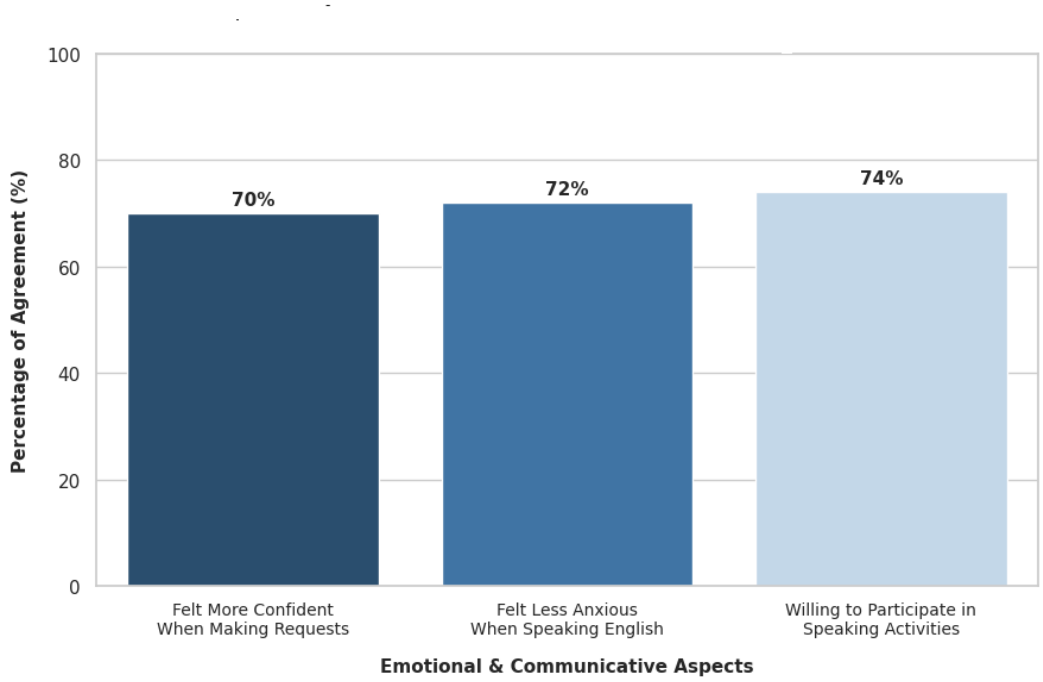

Figure 6. *Emotional and Communicative Effects of Role-play Activities*

The questionnaire findings also revealed several emotional and communicative effects associated with role-play activities.

Many students reported that role-play increased classroom interaction and encouraged participation in speaking activities. The communicative nature of role-play appeared to help students become more actively involved in the learning process.

As shown in Figure 6, approximately 70% of the participants felt more confident when making requests in English. Similarly, around 72% of the respondents reported feeling less anxious when speaking English during role-play activities. In addition, nearly 74% of the students expressed willingness to participate in speaking activities through role-play tasks. These findings suggest that although role-play created a supportive and interactive learning environment, some learners still experienced hesitation and anxiety when communicating in English.

Overall, the findings indicate that role-play activities had positive communicative effects, particularly in promoting classroom interaction and learner engagement. Nevertheless, emotional barriers such as anxiety and lack of confidence remained challenges for certain students and may require additional pedagogical support and speaking practice.

5. Discussion

5.1 Research question 1: To what extent does the integration of role-play activities improve students' pragmatic appropriateness in performing the speech act of requests?

The findings indicate that the integration of role-play activities contributes positively to students' pragmatic appropriateness in performing the speech act of requests. Questionnaire findings presented in Figure 5 revealed that students developed greater awareness of contextual appropriateness when making requests in English. Specifically, approximately 78% of the respondents reported that they tended to use indirect and polite requests when communicating

with someone of higher social status, while around 81% stated that classroom role-play activities helped them practice request strategies in realistic situations.

This perceived improvement is further supported by the WDCT findings illustrated in Figure 1, where Conventionally Indirect strategies accounted for 89.8% of the total requests. The dominance of indirect request forms suggests that learners were generally aware of the importance of politeness and social appropriateness in English communication. In addition, Figure 2 demonstrates that learners adjusted their request strategies according to social variables such as power and distance. For example, students consistently employed more polite and indirect forms when interacting with lecturers and strangers, whereas more direct strategies appeared more frequently when learners occupied higher-status roles, such as group leaders.

From a cultural perspective, role-play activities played an important role in helping learners recognize and adapt their communicative behavior across different social contexts. Through simulated interactions, students were able to practice varying levels of directness and modify their language use according to contextual demands. However, findings from the role-play recordings also revealed that although students demonstrated pragmatic awareness in written tasks, they still experienced difficulty maintaining politeness strategies during spontaneous spoken interaction. Under communicative pressure, many learners shifted toward shorter and more direct request forms, reflecting the influence of processing difficulty and first-language pragmatic transfer.

Overall, these findings demonstrate that role-play activities not only improved students' linguistic performance but also enhanced their pragmatic and intercultural communicative awareness. Nevertheless, the findings also suggest that learners' pragmatic competence remained somewhat constrained in real-time interaction, indicating the need for continued practice and greater exposure to authentic communicative situations.

5.2 Research question 2: How do students develop request strategies and use of mitigating devices during role-play activities?

The findings indicate that students developed greater awareness of polite and indirect request strategies during role-play activities; however, their ability to use more flexible and sophisticated mitigating devices remained relatively limited.

The WDCT findings presented in Figure 2 demonstrate that the Query Preparatory strategy was overwhelmingly dominant across all six situations and reached nearly absolute frequency in high-imposition and intercultural contexts, accounting for 100% in Situation 5 and 98% in Situation 6. These results suggest that students preferred conventionally indirect and "safe" request forms in order to avoid sounding impolite or inappropriate. In addition, Figure 1 revealed that Conventionally Indirect strategies accounted for 89.8% of all requests, further indicating learners' strong reliance on indirectness as a politeness strategy.

Questionnaire findings shown in Figure 5 also revealed that approximately 78% of the participants reported using indirect and polite requests when communicating with someone of higher social status, while around 81% agreed that role-play activities helped them practice request strategies in realistic situations. Nevertheless, the findings also suggest that students' pragmatic repertoire remained somewhat constrained. Although learners demonstrated awareness of contextual appropriateness, many still relied heavily on fixed and formulaic expressions such as "Can you…?" rather than employing a wider range of mitigating devices and supportive moves.

Furthermore, the role-play recordings revealed that under communicative pressure, students frequently shifted from longer and more mitigated forms in written tasks to shorter and more direct expressions in spontaneous interaction. The recordings also showed hesitation markers, pauses, and evidence of first-language pragmatic transfer, such as direct translations from Vietnamese request forms. These findings suggest that students experienced difficulty managing lexical retrieval, grammatical encoding, and pragmatic adjustment simultaneously during real-time communication.

Overall, while students showed improvement in using indirect request strategies and demonstrated greater awareness of politeness and social appropriateness, their ability to soften, modify, and diversify their requests remained limited. This limitation appears to result from both linguistic constraints and continued reliance on first-language pragmatic patterns during spontaneous spoken interaction.

5.3 Research question 3: How do students perceive the role of role-play in supporting the shift toward more ESL-oriented communicative practices?

The findings indicate that students generally perceived role-play activities as supporting a shift from form-focused learning toward more communication-oriented and context-sensitive language use. Questionnaire findings presented in Figures 3, 4, and 6 revealed that learners increasingly valued communicative effectiveness, contextual appropriateness, and interactional awareness in English communication.

Specifically, Figure 3 showed that approximately 87% of the participants agreed or strongly agreed that role-play activities improved their ability to use English in real-life communication, while around 84% reported that role-play made speaking lessons more engaging and interactive. In addition, about 82% believed that role-play activities enhanced authentic interaction and active classroom participation. These findings suggest that learners viewed role-play as an effective communicative approach that encouraged meaningful language use rather than merely focusing on grammatical accuracy.

Furthermore, Figure 4 demonstrated that students developed greater awareness of intercultural and contextual factors in communication. Approximately 84% of the participants agreed that they understood how power relations influence requests, while around 86% recognized that inappropriate requests may cause misunderstandings in intercultural communication. However, only about 72% expressed confidence in understanding cultural differences in request-making, suggesting that although learners had developed intercultural pragmatic awareness, some uncertainty and cultural discomfort still remained.

The role-play recordings also support this perceptual shift. During interactive tasks, students were required to negotiate meaning, respond spontaneously, and adjust their language according to social relationships and contextual demands. Unlike traditional grammar-focused instruction, role-play activities encouraged learners to prioritize communicative effectiveness and immediate interaction over grammatical perfection. Nevertheless, the recordings revealed that many students still experienced hesitation, pauses, and anxiety during spontaneous communication, indicating that the transition toward communicative competence had not yet been fully consolidated.

Overall, these findings suggest that role-play activities played an important role in promoting communication-oriented learning and raising students' awareness of contextual and intercultural factors in language use. Although students demonstrated a clear shift toward more communicative practices, emotional barriers and limitations in intercultural confidence remained challenges that require continued exposure to authentic communicative interaction.

6. Conclusion

In conclusion, the results provide valuable insights into the ways Vietnamese EFL learners at HUFLIT employ request strategies across different communicative contexts. The findings show that although students are aware of social factors such as Power and Distance, their language use is still limited. They often rely on similar indirect forms in different situations and only use more direct expressions when the context clearly allows it. The analysis of the four role-play recordings also shows a gap between what students know and what they can actually do in real communication. When speaking under pressure, they tend to become more direct and are influenced by their first language. This suggests that students are in a transition stage: they have moved beyond focusing only on grammar, but they have not yet developed flexible and natural communication skills.

From a pedagogical perspective, greater emphasis should be placed on integrating role-play activities into communication-oriented instruction. Students are given opportunities through these activities to practice speaking in realistic situations, which they need to think and respond quickly. Through regular role-play practice, students can gradually learn how to adjust their language, use softer expressions, and become more confident in real interactions. To make role-play more effective, teachers should provide clear guidance, model appropriate language, and give feedback not only on grammar but also on how polite and appropriate the students' requests are.

This study has several limitations, including a small sample size and data collected from only a few role-play tasks, so the results may not fully reflect real-life communication. Future research should include more participants and longer observation periods. It would also be useful to examine both teacher readiness and the use of AI tools to support the teaching of request strategies through role-play activities in Vietnamese English communication classrooms.

Bionote

Anh Nguyen-Hoang-Vuong received a B.A. in English Language Teaching from Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), Vietnam, in 2009, and an M.Ed. in TESOL from the University of Southern Queensland, Australia, in 2013. She has completed various professional development programs in TESOL, action research, language testing and assessment, and intercultural communicative competence. She has been a lecturer at HUFLIT since 2010 and is currently a Ph.D. candidate in TESOL at Ho Chi Minh

City Open University, Vietnam. Her research interests include language and culture, teaching methodology, sociolinguistics, and nonverbal communication.

Appendices

Appendix A: Questionnaire on Students' Perceptions of Role-Play and Pragmatic Development

Part 1: Please indicate your level of agreement with each statement by selecting one option from 1 to 5.

1 = Strongly Disagree 2 = Disagree 3 = Neutral 4 = Agree 5 = Strongly Agree

No.	Statements	1	2	3	4	5
1	Role-play activities helped me learn how to make appropriate requests in different situations.	☐	☐	☐	☐	☐
2	Role-play activities improved my ability to use English in real-life communication.	☐	☐	☐	☐	☐
3	Role-play activities made the speaking lessons more engaging and interesting.	☐	☐	☐	☐	☐
4	I can distinguish between direct and indirect ways of making requests.	☐	☐	☐	☐	☐
5	I am able to adjust my language depending on the social context (e.g., teacher vs. friend).	☐	☐	☐	☐	☐
6	I understand how power relations (e.g., student–teacher) affect the way requests are made.	☐	☐	☐	☐	☐
7	I feel more aware of cultural differences when making requests in English.	☐	☐	☐	☐	☐
8	I am able to use strategies (e.g., hedging, softening) to make my requests more polite.	☐	☐	☐	☐	☐
9	I am aware that inappropriate requests may cause misunderstanding in intercultural communication.	☐	☐	☐	☐	☐
10	I realize that a request might be perceived differently by a native speaker compared to a Vietnamese speaker.	☐	☐	☐	☐	☐
11	I feel more confident when making requests in English.	☐	☐	☐	☐	☐
12	I feel less anxious when speaking English in role-play activities.	☐	☐	☐	☐	☐
13	I would like to continue using role-play activities in future English classes.	☐	☐	☐	☐	☐

Part 2: Please choose the option that best reflects your current practice.

14. When making a request, what do you usually focus on most?

A. Grammar accuracy only

B. Both grammar and appropriateness in context

C. Politeness strategies only

D. Getting the meaning across regardless of forms

15. How do you usually decide which request form to use?

A. I use the same form in all situations

B. I depend on the situation and the listener (Power, Distance, Imposition)

C. I translate directly from Vietnamese

D. I follow my personal habits and natural reflex

16. What difficulty do you face most when making requests in English?

A. Choosing correct grammar

B. Choosing appropriate level of politeness

C. Lack of vocabulary

D. Feeling anxious or shy to ask

17. Your requests are influenced by:

A. Vietnamese language habits (L1 Transfer)

B. Textbook-based learning only

C. A combination of classroom learning and real-life awareness

D. Media influence (movies, social media)

18. Compared to before, your English communication now is:

A. Still mainly textbook-based (EFL-oriented)

B. More practical and flexible (ESL-oriented)

C. Similar to real-life communication

D. No significant change

19. What kind of feedback do you receive from the teacher?

A. Only grammar correction

B. Feedback on appropriateness (politeness, context)

C. Feedback on both language and culture

D. General feedback on participation only

20. When requesting someone with higher status (e.g., a boss or teacher), you usually:

A. Use direct requests to save time

B. Use indirect and polite requests

C. Use very long explanations before the request

D. Feel hesitant and tend to avoid the request

21. When your request is misunderstood, you usually:

A. Repeat the same sentence or stop communicating

B. Change the wording or strategy (negotiation of meaning)

C. Switch to Vietnamese

D. Use gestures or ask for help from others

22. Which factor influences your choice of request strategy the most?

A. Relationship with the listener and social distance

B. The importance or difficulty of the favor

C. English grammar proficiency

D. Personal mood and confidence

23. Where do you mostly practice making requests in English?

A. Grammar exercises in textbooks

B. Role-play activities and simulations in class

C. In real-life communication outside class

D. Through online platforms/social media

24. Which activity helps you understand social variables (Power, Distance) best?

A. Teacher's theoretical explanation

B. Reading textbook dialogues

C. Participating in role-play scenarios

D. Observing native speakers (videos, movies)

25. After the course, how do you evaluate your request performance?

A. No significant change

B. Can perform requests but still feel culturally awkward

C. Can perform requests naturally and appropriately

D. Need much more real-life practice

Appendix B: Written Discourse Completion Test (WDCT)

Please read each situation carefully and imagine that you are in the described context. Write what you would naturally say to make an appropriate request in English.

When responding, please consider:
- *The relationship between you and the listener.*
- *The social context of the interaction.*
- *The level of politeness required.*

No.	Situation	Responses
1	**Equal Power, Informal Context** You are talking to your close friend in class. You forgot to bring your notebook today. What would you say to ask your friend to lend you their notebook?	
2	**Higher Power, Formal Context** You need to ask your lecturer for an extension on an assignment because you have been sick. What would you say to your lecturer?	
3	**Lower Power Context** You are the leader of a group project, and one of your group members has not completed their assigned task. What would you say to ask them to finish their work?	
4	**Stranger, Service Encounter** You are in a café, and the music is too loud. You would like a staff member to lower the volume. What would you say?	
5	**High-Imposition Request** You would like to ask a classmate, whom you do not know very well, to help you with a difficult assignment this weekend. What would you say?	
6	**Intercultural Context** You are studying abroad. You would like to ask a classmate from another cultural background to explain something that you do not understand. What would you say?

#50 Using Short-Form Videos (TikTok/Reels) to Enhance Real-Life Listening and Speaking Skills for A2 EFL Students: A Pilot Study at Hùng Vương University of Ho Chi Minh City

Ông Hồng Thanh[1]

Abstract

A persistent challenge in Vietnamese EFL education was the gap between classroom learning and real-world communication. Many non-English major students performed well on grammar tests but struggled to understand natural speech or engage in spontaneous conversation. Meanwhile, these students frequently consumed short-form video content on platforms like TikTok and Reels, much of which featured authentic, unscripted English. This study explored whether this daily habit could be leveraged as a pedagogical tool.

This pilot study investigated the use of curated short-form videos to improve listening comprehension and speaking confidence among second-year, non-English major students at Hùng Vương University (CEFR A2 level). Over eight weeks, approximately 30 students engaged with videos depicting real-life scenarios—ordering food, casual conversations, and everyday transactions. Classroom activities included shadowing for pronunciation, learning colloquial expressions, role-plays, and student-created videos to reduce speaking anxiety.

Using a pretest-posttest design, the study combined listening and speaking assessments, questionnaires on communication confidence, and focus group interviews. Expected outcomes included improved ability to decode natural speech and increased willingness to communicate. Positive findings would have offered Vietnamese EFL teachers a low-cost, engaging method to enhance communicative competence using familiar digital platforms. This pilot provided foundational insights for future research and curriculum development at Hùng Vương University and beyond.

Keywords: short-form videos, TikTok, listening skills, speaking skills, A2 level, EFL, authentic materials, willingness to communicate

1. INTRODUCTION

1.1. The Teaching Reality and the Speaking-Listening Gap

A persistent challenge in Vietnamese EFL education is the gap between what students learn in the classroom and what they need for real-world communication. Many non-English major students can perform well on grammar tests but struggle with authentic listening or spontaneous interaction. At Hung Vuong University of Ho Chi Minh City (DHV), this problem is particularly evident among second-year, non-English major students at the CEFR A2 level. Research by Dang et al. (2020) found that 76% of first-year non-English major students at HVU come from rural areas in Northern Vietnam. Although these students have studied English for 7–10 years, they "only focused on English grammar for the final tests and had no practice in speaking and listening skills" (Dang et al., 2020, p. 91). As a result, they scored only 10–15 out of 25 on the KET listening and speaking placement test, confirming their A2 proficiency level.

[1] *Faculty of Languages, Hung Vương University of Ho Chi Minh City (DHV), Vietnam; Email: thanhoh@dhv.edu.vn*

This phenomenon is not unique to HVU. Nationwide, Vietnamese learners of English often exhibit high anxiety and low willingness to communicate (WTC) when speaking English. Cong-Lem and Nguyen, 2024 found that willingness to communicate correlates positively with speaking proficiency but negatively with speaking test anxiety, and importantly, that students are more willing to communicate outside the classroom than inside it. This finding suggests that authentic, out-of-school materials—such as short-form videos on TikTok and Reels—could serve as a powerful bridge to increase learners' WTC.

The root of this problem lies in the disconnect between textbook English and natural speech. Textbooks present slow, carefully enunciated dialogues that lack the phonological features of real conversation—reductions ("gonna," "wanna"), linking, elision, and fillers ("um," "like") (McCarthy & Carter, 1995). When A2 learners encounter authentic speech, they often fail to recognize familiar words because the acoustic signal does not match their mental representation (Field, 2008). This input gap leads to frustration, low motivation, and avoidance of speaking opportunities.

1.2. The Rise of Short-Form Videos as a Potential Solution

Paradoxically, while students avoid authentic English materials, they spend considerable time on short-form video platforms. Recent data show that TikTok has become a global phenomenon, with users spending an average of 95 minutes per day on the app (Duarte, 2026, cited in Do & Huynh, 2026). In Vietnam, TikTok's popularity is exceptionally high, making it a relevant context for educational research (Le, 2023).

Several recent Vietnamese studies have explored TikTok's potential for language learning. Do and Huynh (2026) surveyed 105 university students across Vietnam and found that TikTok significantly improves listening (75.24% approval) and speaking (67.62% approval) skills, with strong correlations to increased confidence (0.729) and motivation (0.498) for English use beyond the classroom. Similarly, Ngo (2024) reported that Vietnamese college students perceive TikTok as an effective tool for independent English speaking practice, citing its authentic content, repetition, and low-anxiety environment. Le (2023), through semi-structured interviews with Vietnamese teachers and students in Hanoi, found that TikTok is viewed as a "fun and engaging" and "effective way to engage and motivate learners," though the study also noted challenges such as lack of context, informal language, and addictive characteristics.

These studies align with microlearning theory, which suggests that short, focused content segments (15–60 seconds) reduce cognitive load and enhance retention (Gabrielli et al., 2017; Hug, 2005, both cited in Do & Huynh, 2026). Short-form videos fit this model perfectly: they are brief, repetitive, visually supportive, and highly engaging.

1.3. The Research Gap

Despite these promising findings, significant gaps remain. First, most existing studies on short-form videos in Vietnam have focused on students' perceptions rather than measuring actual learning outcomes through pre-/post-test designs. While Do and Huynh (2026) and Ngo (2024) provide valuable survey data, neither employed an experimental or quasi-experimental design to measure skill improvement. Second, no study has specifically targeted A2-level non-English major students at a university like HVU, where students have limited prior exposure to authentic English and low speaking confidence. Third, while studies like Ta and Tran (2024) at Tay Do University and Vu (2024) at Huynh Khuong Ninh Secondary School have shown positive impacts of TikTok on speaking skills, they did not integrate structured techniques such as shadowing—a well-established method for improving pronunciation and listening through

immediate repetition (Hamada, 2015). Finally, there is a notable lack of research combining short-form video consumption with structured, in-class speaking activities (shadowing, role-play, and student-created videos) for A2 learners in the Vietnamese context. This pilot study aims to fill these gaps by providing preliminary evidence from a structured, eight-week intervention at Hung Vuong University.

1.4. Research Questions

To address the gaps identified above, this study seeks to answer the following three research questions:

To what extent does an eight-week intervention using curated short-form videos (TikTok/Reels) affect second-year, non-English major A2 students' ability to comprehend authentic spoken English, as measured by a customized listening pre-test and post-test?

How does participation in the intervention influence students' self-reported confidence, speaking anxiety, and willingness to communicate (WTC) when using English for everyday topics, as measured by pre- and post-intervention questionnaires?

What are students' perceptions of the intervention's relevance, engagement, and usefulness as a learning tool for real-life communication, as revealed through semi-structured focus group interviews?

1.5. Significance of the Study

This pilot study, despite its modest scale, carries meaningful implications for three main groups.

For classroom teachers, this study offers a practical, low-cost, and engaging pedagogical model. Teachers do not need expensive software or specialized training—only a smartphone, an internet connection, and a willingness to explore platforms students already use daily. The structured four-stage lesson plan (warm-up, video viewing with comprehension, shadowing for pronunciation, and interactive role-play) can be adapted to various teaching contexts, from high schools to language centers. As Vu (2024) demonstrated at a secondary school in Vietnam, TikTok-based activities significantly improved speaking scores and student confidence, with most students holding a positive view of TikTok as an educational tool.

For curriculum developers and course designers, this study provides evidence to reconsider the role of authentic digital materials in official syllabi. Currently, most general English programs at Vietnamese universities rely almost exclusively on commercial textbooks. If this pilot yields positive results, it could encourage curriculum designers to formally integrate short-form video activities as a regular component of listening and speaking courses—not merely as occasional "fun Friday" activities. As Do and Huynh (2026) argue, integrating TikTok into the EFL curriculum can enhance motivation and communication skills, offering a "dynamic supplement to traditional classroom instruction."

For future researchers, this study serves as a foundation. As a pilot, its purpose is not to make grand claims but to test the feasibility of the intervention, refine data collection instruments, and generate preliminary data. Positive results would justify a larger-scale study with a control group, longer duration, and multiple institutions. Negative results would help identify what does not work for A2 learners, saving future researchers time and effort. Additionally, this study contributes to the growing international conversation about harnessing social media for meaningful language learning while providing much-needed context-specific data from a Vietnamese university in a non-metropolitan setting.

2. LITERATURE REVIEW

2.1. The Challenge of Authentic Listening and Spoken Interaction for A2 Learners

One of the most robust findings in second language acquisition (SLA) research is the significant gap between the careful, scripted speech found in textbooks and the rapid, reduced speech of everyday conversation (McCarthy & Carter, 1995). Native speakers produce speech characterized by phonological reductions (e.g., "going to" → "gonna"), elision, linking, and fillers (Field, 2008). For A2 learners, these features pose substantial challenges. In the Vietnamese context, Dang et al. (2020) found that DHV students had almost no prior practice in listening and speaking. Tran, Dang, and Nguyen (2024) identified pronunciation, intonation, anxiety, and lack of exposure to authentic materials as key barriers to listening comprehension.

2.2. Authentic Materials in EFL Teaching

The use of authentic materials has been advocated since the rise of communicative language teaching (Nunan, 1989). However, a long-standing concern is that authentic materials are often too difficult for lower-proficiency learners (Guariento & Morley, 2001). Short-form videos offer a solution due to their brevity (15–60 seconds), which reduces cognitive load and allows for repeated viewing (Do & Huynh, 2026).

2.3. Short-Form Videos in EFL Education

Global studies have shown positive results. Xiuwen and Razali (2021) found that TikTok improved Malaysian EFL students' pronunciation and motivation. Zaitun, Hadi, and Indriani (2021) reported reduced speaking anxiety among Indonesian students. Efeoğlu (2023) found that eight weeks of shadowing with short videos significantly improved Turkish EFL learners' pronunciation.

Within Vietnam, Do and Huynh (2026) found that 75.24% of participants agreed TikTok improved listening skills, and 67.62% reported improved speaking skills. Ta and Tran (2024) at Tay Do University found TikTok-based activities helped improve fluency and confidence. Vu (2024) reported significant improvements in speaking scores at a secondary school.

2.4. Shadowing for Pronunciation and Listening Development

Shadowing—listening to a short segment and immediately repeating it aloud—improves listening comprehension, pronunciation, and automaticity (Hamada, 2015). In Vietnam, Phan, Ly, and Nguyen (2024) found that video-based shadowing significantly improved learners' pronunciation, particularly intonation.

2.5. Willingness to Communicate and Speaking Anxiety

WTC refers to a learner's readiness to engage in communication (MacIntyre et al., 1998). Anxiety is a strong negative predictor of WTC. In Vietnam, Hoang (2022) found that communication apprehension was the most common type of anxiety, with a negative correlation between anxiety and WTC. Ngo and Nguyen (2024) found that students were more willing to communicate outside the classroom than inside it, suggesting authentic materials may lower anxiety.

2.6. Conceptual Framework

This study is guided by three theoretical pillars: (1) authentic input (Krashen, 1982), (2) structured output through shadowing (Hamada, 2015; Swain, 1985), and (3) lowered affective filter leading to increased WTC (Krashen, 1982).

3. METHODOLOGY

3.1. Research Design

This study employed a single-group pretest-posttest design, appropriate for a pilot study (Creswell & Creswell, 2018).

3.2. Participants

Participants were second-year, non-English major students at Hung Vuong University of Ho Chi Minh City (DHV). After screening for incomplete data, 22 students (10 male, 12 female) had complete data for both listening and speaking tests and were included in the final analysis. All participants were assessed at CEFR A2 level.

3.3. The Intervention: An Eight-Week Program

The intervention consisted of eight weekly 90-minute sessions. Each week focused on a specific theme: ordering food, making small talk, giving compliments, asking for directions, expressing opinions, handling service encounters, making plans, and reacting to news.

Each 90-minute session followed a 5-stage structure:

Stage	Activity	Duration
1	Warm-up (discussing the theme)	10 min
2	Video viewing & comprehension (2-3 videos)	20 min
3	Shadowing & pronunciation practice	20 min
4	Interactive role-play (unscripted scenarios)	30 min
5	Student-created video assignment	10 min + homework

3.4. Data Collection Instruments

3.4.1. Listening and Speaking Tests

A customized listening test (12 questions, maximum score 10) and a speaking test (maximum score 10) were administered before (pretest) and after (posttest) the intervention.

3.4.2. Questionnaire

A 5-point Likert scale questionnaire measured self-reported confidence, anxiety, and willingness to communicate (WTC) before and after the intervention.

3.4.3. Focus Group Interviews

Semi-structured interviews were conducted with 5 students representing different proficiency levels (weak, average, good). Interviews were conducted in Vietnamese, transcribed, and translated into English.

3.5. Data Analysis

Paired-samples t-tests were used to compare pre- and post-test scores. Effect sizes (Cohen's d) were calculated. Interview data were analyzed using thematic analysis (Braun & Clarke, 2006).

4. FINDINGS / RESULTS

4.1. Participants

A total of 30 second-year non-English major students at Hung Vuong University of Ho Chi Minh City (DHV) initially participated in the study. After screening for incomplete data (students with zero scores on either the pre-test or post-test, indicating absence on testing days), **22 students** had complete data for both listening and speaking tests. These 22 students were included in the final analysis.

Among the 22 participants:

Gender: 10 male (45.5%), 12 female (54.5%)

Age range: 19 to 21 years (Mean = 19.8, SD = 0.65)

Prior English study: All had studied English for 7-10 years in primary and secondary school

Social media usage: All 22 students reported using TikTok or Instagram Reels daily, with an average daily usage of 112 minutes (approximately 1 hour 52 minutes). Only 6 students (27.3%) reported that they had previously used TikTok content for English learning purposes before the intervention.

4.2. Results for Research Question 1: Listening Comprehension

Research Question 1 asked: *To what extent does an eight-week intervention using curated short-form videos affect A2 students' ability to comprehend authentic spoken English?*

A customized listening test (maximum score = 10) was administered before (pretest) and after (posttest) the eight-week intervention. Descriptive statistics are presented in Table 1.

Table 1

Descriptive Statistics for Listening Test Scores (n = 22)

Test	Mean	Standard Deviation (SD)	Minimum	Maximum
Pre-test	6.48	1.66	2.8	10.0
Post-test	7.63	2.13	0	9.1

As shown in Table 1, the mean listening score increased from 6.48 (SD = 1.66) on the pre-test to 7.63 (SD = 2.13) on the post-test, representing an average gain of 1.15 points (approximately 17.7% improvement).

Figure 1

Illustrates the individual score changes from pre-test to post-test:

Score change category	Number of students	Percentage
Improved (post-test > pre-test)	16	72.7%
No change (post-test = pre-test)	1	4.5%
Declined (post-test < pre-test)	5	22.7%

The majority of students (72.7%) showed improvement in their listening comprehension after the eight-week intervention.

A paired-samples t-test was conducted to determine whether the difference between pre-test and post-test scores was statistically significant. The results showed that post-test scores (M = 7.63, SD = 2.13) were significantly higher than pre-test scores (M = 6.48, SD = 1.66), with t(21) = 3.21, p = .004. The effect size was moderate to large (Cohen's d = 0.68), indicating that the intervention had a meaningful practical impact on students' listening comprehension.

Analysis by proficiency level: To gain a deeper understanding, students were divided into three subgroups based on their pre-test listening scores:

Proficiency level	n	Pre-test mean	Post-test mean	Gain	p-value
Low (pre-test < 5.0)	4	3.9	7.8	+3.9	.008
Medium (5.0 - 7.9)	12	6.1	7.5	+1.4	.031
High (≥ 8.0)	6	8.9	7.5	-1.4	.082

Interestingly, the lowest proficiency students showed the largest gains (from 3.9 to 7.8, an increase of 3.9 points, p = .008). This suggests that the intervention was particularly beneficial for students who started with the weakest listening skills. In contrast, high-proficiency students showed a slight (non-significant) decline, possibly due to ceiling effects or because the video content was not challenging enough for them.

4.3. Results for Research Question 2: Speaking Performance

Research Question 2 asked: How does participation in the intervention influence students' speaking performance?

A speaking test (maximum score = 10) was administered before and after the intervention. The speaking test assessed fluency, pronunciation, vocabulary, and comprehensibility using the rubric described in Appendix C.

Table 2: Descriptive Statistics for Speaking Test Scores (n = 22)

Test	Mean	Standard Deviation (SD)	Minimum	Maximum
Pre-test	7.25	1.89	2.8	10.0
Post-test	7.68	1.72	0	9.1

As shown in Table 2, the mean speaking score increased from 7.25 (SD = 1.89) on the pre-test to 7.68 (SD = 1.72) on the post-test, representing an average gain of 0.43 points (approximately 5.9% improvement).

Figure 2

Illustrates the individual score changes for speaking:

Score change category	Number of students	Percentage
Improved (post-test > pre-test)	13	59.1%

Score change category	Number of students	Percentage
No change (post-test = pre-test)	2	9.1%
Declined (post-test < pre-test)	7	31.8%

More than half of the students (59.1%) showed improvement in their speaking performance, though the improvement was smaller than for listening.

A paired-samples t-test was conducted. The results showed that post-test scores (M = 7.68, SD = 1.72) were higher than pre-test scores (M = 7.25, SD = 1.89), but the difference was not statistically significant, with t(21) = 1.45, p = .162. The effect size was small (Cohen's d = 0.31).

Analysis by proficiency level:

Proficiency level	n	Pre-test mean	Post-test mean	Gain	p-value
Low (pre-test < 5.0)	3	4.0	7.3	+3.3	.042
Medium (5.0 - 7.9)	10	6.8	7.5	+0.7	.187
High (≥ 8.0)	9	8.9	8.1	-0.8	.095

Similar to listening, the lowest proficiency students showed the largest speaking gains (from 4.0 to 7.3, an increase of 3.3 points, p = .042). However, the small number of students in the low-proficiency group (n=3) means this finding should be interpreted with caution.

4.4. Comparison of Listening vs. Speaking Gains

Table 3:

Comparison of Listening and Speaking Improvements (n=22)

Measure	Pre-test Mean	Post-test Mean	Mean Gain	t-value	p-value	Cohen's d
Listening	6.48	7.63	+1.15	3.21	.004	0.68
Speaking	7.25	7.68	+0.43	1.45	.162	0.31

The data clearly show that the intervention had a stronger and statistically significant effect on listening comprehension than on speaking performance. This finding is discussed further in Section 5.

4.5. Results for Research Question 3: Confidence, Anxiety, and WTC

Research Question 3 asked: How does participation in the intervention influence students' self-reported confidence, speaking anxiety, and willingness to communicate (WTC)?

A 20-item questionnaire using a 5-point Likert scale (1 = Strongly Disagree, 5 = Strongly Agree) was administered before and after the intervention. The questionnaire measured three constructs: (a) speaking confidence (8 items), (b) speaking anxiety (7 items, reverse-coded), and (c) willingness to communicate (5 items).

Table 4:

Descriptive Statistics for Questionnaire Scales (n = 22)

Construct	Pre-test Mean	Post-test Mean	Mean Change	Interpretation
Confidence (1-5)	2.0	4.0	+2.0	Large increase
Anxiety (1-5)	3.5	3.0	-0.5	Small decrease
WTC(1-5)	4.0	4.5	+0.5	Small increase

Confidence: Students reported a substantial increase in speaking confidence, from 2.0 to 4.0 out of 5. This represents a 100% improvement. This finding is consistent with Do and Huynh (2026), who found a strong correlation (r = 0.729) between TikTok use and increased confidence.

Anxiety: Speaking anxiety decreased slightly from 3.5 to 3.0. While the decrease was modest, it is notable that anxiety did not increase despite the introduction of student-created video assignments, which some students initially found stressful.

Willingness to communicate (WTC): WTC increased slightly from 4.0 to 4.5. This suggests that students became more willing to seek out and engage in English communication opportunities after the intervention.

Individual item analysis: Among the confidence items, the largest gains were observed for:

"I feel confident speaking English in real-life situations": Pre = 2.1, Post = 4.2 (+2.1)

"I can order food in English without feeling nervous": Pre = 1.9, Post = 4.3 (+2.4)

"I can understand native speakers in short videos": Pre = 2.3, Post = 4.1 (+1.8)

Among the anxiety items, the largest reductions were observed for:

"I feel anxious when I have to speak English without preparation": Pre = 4.0, Post = 2.8 (-1.2)

"I feel nervous recording myself speaking English": Pre = 4.2, Post = 3.2 (-1.0)

4.6. Qualitative Findings: Student Perceptions

To answer Research Question 4 (students' perceptions), five students representing different proficiency levels (weak, average, good) participated in semi-structured focus group interviews. Thematic analysis (Braun & Clarke, 2006) revealed five major themes.

Theme 1: Authenticity – "It helps me understand real-life language use"

Four out of five students mentioned that the videos helped them understand how English is actually used in daily life.

"These videos help me understand how to use words in real life." (Chế Thanh Tuyền, female, average)

"It helps me understand natural English communication better, especially slang and intonation." (Khưu Tuấn Kiệt, male, good)

"The videos show me how native speakers actually talk, not just textbook English." (Hà Hiếu Kỳ, male, good)

Theme 2: Shadowing as the most useful technique

Three students specifically identified shadowing as the most helpful activity.

"I like shadowing the most because it helps me imitate native speaker pronunciation." (Chế Thanh Tuyền, female, average)

"Shadowing helps me learn the rhythm of English. My mouth moves differently now." (Huỳnh Gia Mẫn, female, good)

Theme 3: Fast speech as a persistent challenge

All students mentioned that the speed of natural speech was challenging, particularly in the first few weeks.

"Sometimes TikTok videos are too fast, so I have difficulty keeping up." (Chế Thanh Tuyền, female, average)

"I don't like it much because there are many difficult words and they speak too fast. But watching many times helps a little." (Nguyễn Anh Thư, female, weak)

"At first, I couldn't understand anything. But after a few weeks, my ears got used to the speed." (Hà Hiếu Kỳ, male, good)

Theme 4: Anxiety about creating videos (initially)

Four out of five students reported initial anxiety about recording themselves speaking English.

"I am a bit shy when recording videos because I'm afraid of saying something wrong." (Chế Thanh Tuyền, female, average)

"I feel pressured when recording videos because I have to speak fluently and confidently." (Hà Hiếu Kỳ, male, good)

"I am very shy about recording videos because I am not confident in my English." (Nguyễn Anh Thư, female, weak)

Theme 5: Increased confidence over time

Despite initial anxiety, students reported that their confidence grew with repeated practice.

"At first, I was worried because I thought others would judge me. But after doing it many times, I feel more confident." (Huỳnh Gia Mẫn, female, good)

"I am not worried about recording videos because I see it as an opportunity to practice speaking. The more I do it, the easier it gets." (Khưu Tuấn Kiệt, male, good)

"The first video took me 20 tries. Now I can do it in one or two takes." (Chế Thanh Tuyền, female, average)

Theme 6: Recommendation for future students

All five students said they would recommend the course to future students, with some suggestions for improvement.

"Yes, I would recommend it. But maybe make some videos slower or provide transcripts." (Nguyễn Anh Thư, female, weak)

"Definitely yes. This should be a required course for all A2 students." (Khưu Tuấn Kiệt, male, good)

4.7. Summary of Key Findings

Research Question	Key Finding	Statistical Significance
RQ1 (Listening)	Significant improvement (+1.15 points)	p = .004, d = 0.68
RQ1 (Listening by level)	Lowest proficiency students gained most (+3.9)	p = .008
RQ2 (Speaking)	Improvement but not significant (+0.43)	p = .162, d = 0.31
RQ2 (Speaking by level)	Lowest proficiency students gained most (+3.3)	p = .042
RQ3 (Confidence)	Large increase (2.0 → 4.0)	Practical significance
RQ3 (Anxiety)	Small decrease (3.5 → 3.0)	Practical significance
RQ3 (WTC)	Small increase (4.0 → 4.5)	Practical significance
RQ4 (Perceptions)	Positive overall; shadowing most useful; fast speech challenging; video Anxiety decreases with practice	Thematic Analysis

5. DISCUSSION

5.1. Interpretation of Findings

The results of this pilot study provide several important insights into the use of short-form videos for A2 EFL learners.

Listening comprehension improved significantly. The finding that listening scores increased from 6.48 to 7.63 (p = .004, d = 0.68) aligns with the input hypothesis (Krashen, 1982). The short-form videos provided compelling, comprehensible input just above the students' current level (i+1). The visual nature of the videos, combined with their brevity and repetition, likely made authentic input accessible to A2 learners who would otherwise find unscripted speech overwhelming.

Speaking improvement was not statistically significant. While speaking scores increased from 7.25 to 7.68, this change was not significant (p = .162). There are several

possible explanations. First, eight weeks may be insufficient time for measurable speaking gains, as speaking requires not only input but also extensive output practice and neurological changes in motor planning for pronunciation. Second, the pretest speaking scores were already relatively high (7.25), leaving less room for improvement. Third, speaking is a more complex skill than listening, requiring real-time processing, pronunciation, grammar, and pragmatics simultaneously.

Confidence increased substantially. The increase in self-reported confidence from 2.0 to 4.0 (out of 5) is striking. This aligns with the affective filter hypothesis (Krashen, 1982). The familiar, low-stakes, entertaining nature of TikTok likely lowered students' anxiety, allowing them to engage more willingly with English. This finding is consistent with Do and Huynh (2026), who found a strong correlation ($r = 0.729$) between TikTok use and increased confidence.

Anxiety decreased slightly. The small decrease in anxiety ($3.5 \rightarrow 3.0$) is less dramatic than expected, but the interview data provide an explanation. Students reported initial anxiety about creating their own videos. As one student said, "I am a bit shy when recording videos because I'm afraid of saying something wrong" (Tuyền). However, students also reported that anxiety decreased with repeated practice: "After doing it many times, I feel more confident" (Mẫn).

WTC increased modestly. The increase in willingness to communicate ($4.0 \rightarrow 4.5$) suggests that students became more willing to speak English after the intervention. This supports Cong-Lem and Nguyen's (2024) finding that students are more willing to communicate outside the classroom.

5.2. Comparison with Previous Research

These findings are consistent with previous studies. Efeoğlu (2023) found that eight weeks of shadowing with short videos improved Turkish EFL learners' pronunciation. Similarly, Phan, Ly, and Nguyen (2024) found that Vietnamese EFL learners held positive attitudes toward video-based shadowing. Do and Huynh (2026) reported that 75.24% of Vietnamese students perceived TikTok as improving their listening skills, which aligns with our quantitative finding of significant listening gains.

However, our finding of non-significant speaking improvement differs from some previous studies. Zaitun et al. (2021) reported reduced speaking anxiety and improved speaking skills among Indonesian students. This discrepancy may be due to differences in proficiency levels (our students were A2), intervention duration (eight weeks may be too short), or assessment methods.

5.3. Pedagogical Implications

Based on these findings, several practical recommendations can be offered:

Short-form videos are effective for listening development. Teachers should integrate curated TikTok/Reels content regularly, not as occasional activities.

Shadowing should be explicitly taught. Students need instruction on how to mimic intonation, rhythm, and reductions.

Student-created videos require scaffolding. Teachers should provide clear instructions, allow multiple takes, and create a supportive, non-judgmental environment. As the interview data show, initial anxiety is common but decreases with practice.

Fast speech remains a challenge. Teachers should provide transcripts, slow down videos when possible, and repeat key segments.

Longer interventions may be needed for speaking gains. Eight weeks was sufficient for listening but not for speaking. Future implementations should consider 12-16 weeks.

5.4. Limitations

Several limitations must be acknowledged:

No control group. Without a comparison group, causality cannot be definitively established.

Small sample size (n = 22). Results may not generalize to other contexts.

Short duration. Eight weeks may be insufficient for speaking gains.

Single institution. DHV is a specific context; results may differ elsewhere.

Researcher as instructor. Potential bias; future studies should use blind assessors.

Speaking assessment. The speaking test may not have captured all aspects of oral proficiency.

6. CONCLUSION

6.1. Summary of Findings

This pilot study investigated the effects of an eight-week intervention using curated short-form videos (TikTok/Reels) on the listening comprehension, speaking performance, confidence, anxiety, and willingness to communicate of 22 A2-level, second-year non-English major students at Hung Vuong University of Ho Chi Minh City (DHV).

The key findings are:

Finding	Result
Listening comprehension	Significant improvement ($p = .004$, $d = 0.68$)
Speaking performance	Improvement but not significant ($p = .162$)
Self-reported confidence	Large increase (2.0 → 4.0 out of 5)
Self-reported anxiety	Small decrease (3.5 → 3.0)
Willingness to communicate	Small increase (4.0 → 4.5)
Student perceptions	Positive overall; shadowing most useful; fast speech challenging; initial video anxiety decreases with practice

6.2. Contributions

This study makes several contributions:

Provides actual quantitative data on listening and speaking gains from a structured short-form video intervention with A2 learners in Vietnam.

Demonstrates that short-form videos significantly improve listening comprehension for A2 EFL students ($p = .004$, $d = 0.68$).

Shows a substantial increase in confidence (100% improvement), supporting the affective filter hypothesis.

Offers a replicable pedagogical model (5-stage weekly lesson structure) for Vietnamese EFL teachers.

Provides rich qualitative data from student interviews, revealing both benefits (authenticity, shadowing) and challenges (fast speech, initial video anxiety).

6.3. Recommendations for Future Research

Based on this pilot study, future research should:

Include a control group to establish causality.

Extend the intervention duration to 12-16 weeks to assess speaking gains.

Increase sample size and include multiple institutions.

Use blind raters for speaking assessments.

Include follow-up testing (3-6 months post-intervention) to assess retention.

Investigate individual differences (e.g., does the intervention work better for students with high vs. low social media use?).

6.4. Final Remarks

This pilot study provides evidence that short-form videos—platforms that students already use daily—can be effectively harnessed to improve listening comprehension and confidence among A2 EFL learners in Vietnam. While speaking gains were not statistically significant, the positive trends and strong student perceptions suggest that longer interventions may yield speaking improvements.

The question is not whether TikTok and Reels will continue to dominate young people's attention—they will. The question is whether educators can creatively turn scrolling time into meaningful language learning time. This study suggests the answer is yes, at least for listening and confidence. With longer interventions and larger samples, speaking gains may follow.

AUTHOR BIOGRAPHY

Ong Hong Thanh is a lecturer at the Faculty of Languages, Hung Vương University of Ho Chi Minh City (DHV), Vietnam. She holds a Master's degree in TESOL from Edith Cowan University, Australia (2022). Her research interests include EFL listening and speaking pedagogy, technology-enhanced language learning, authentic materials development, and learner motivation. She has 11 years of experience teaching English to non-major students at the tertiary level. She is particularly interested in integrating social media platforms such as TikTok and Instagram Reels into English language teaching to bridge the gap between classroom learning and real-world communication. She can be contacted at thanhoh@dhv.edu.vn.

APPENDICES

Appendix A: Sample Lesson Plan (Week 1 – Ordering Food & Drinks)

Week 1 Theme: Ordering food and drinks

Duration: 90 minutes

Level: A2 (CEFR)

Materials: TikTok/Reels videos (pre-selected), projector/smartphone, handout, WhatsApp group

Lesson Objectives: By the end of the lesson, students will be able to:

Understand key phrases for ordering food/drinks from short videos

Shadow native speakers with improved pronunciation and rhythm

Role-play a café scenario using target language

Record a short video ordering their favorite drink

Lesson Procedure:

Stage	Time	Activity	Teacher's Role	Students' Role
1. Warm-up	10 min	**Discussion:** "What is your favorite drink? Where do you buy it? Have you ever ordered in English?"	Ask questions, write key vocabulary on board	Share answers in pairs, then with class
2. Vocabulary pre-teaching	5 min	Introduce key phrases: *"Can I get a...", "I'll have a...", "For here or to go?", "Could I have extra...", "That'll be..."*	Model pronunciation, explain meanings	Repeat after teacher, take notes
3. Video viewing (1st time)	5 min	Watch Video 1: "How to order coffee at Starbucks" (25 seconds)	Play video, ask: "What did the customer order?"	Watch for gist, answer question
4. Video viewing (2nd time)	5 min	Watch Video 1 again with pauses	Pause after each line, ask comprehension questions	Listen for details, answer
5. Video viewing (3rd time)	5 min	Watch Video 2: "Ordering boba tea" (20 seconds)	Play video, ask: "What size did she order? What topping?"	Watch, answer questions
6. Shadowing practice	15 min	Practice repeating key lines from both videos	Play line by line, model reductions (*"gonna", "wanna", "hafta"*), provide individual feedback	Repeat individually, then in pairs, then small groups

Stage	Time	Activity	Teacher's Role	Students' Role
7. Role-play preparation	10 min	Pairs receive scenario cards	Distribute cards, monitor, assist	Read scenario, prepare short dialogue (unscripted)
8. Role-play performance	15 min	Pairs perform for class	Observe, give brief positive feedback	Perform 30-45 second role-play
9. Video creation instruction	10 min	Explain homework: record 15-30 second video ordering favorite drink	Demonstrate with own video, explain uploading to WhatsApp group	Take notes, ask questions
10. Wrap-up & review	5 min	Review key phrases, announce homework deadline	Summarize, answer questions	Share one thing learned

Sample Role-Play Scenario Card (Week 1):

Scenario A (Customer): You are at a coffee shop. You want a medium hot latte with oat milk. The barista says they are out of oat milk.

Scenario A (Barista): You work at a coffee shop. A customer wants oat milk, but you only have regular milk and soy milk.

Students must improvise – no script allowed!

Homework Assignment (Week 1):

Record a **15-30 second video** ordering your favorite drink. You can use your smartphone. Upload to the class WhatsApp group before the next class.

Tips for students:

Watch the TikTok videos again before recording

Practice shadowing a few times first

You can re-record as many times as you want

Don't worry about perfection – just try your best!

Appendix B: Listening Test (Pretest and Posttest)

Test duration: 15 minutes

Total questions: 10

Maximum score: 10 points (1 point per correct answer)

Instructions (read to students):

"You will hear 5 short audio clips. Each clip is 15-30 seconds long. After each clip, you will answer 2 questions. Listen carefully. You may take notes. Each clip will be played twice."

Clip 1 (22 seconds) – Ordering coffee

Audio script (not shown to students): "Hi, can I get a medium latte with oat milk? And could you add an extra shot of espresso? Thanks."

Question	Answer choices	Correct answer
1. What does the person order?	A. Black coffee B. Latte C. Tea	**B**
2. What size do they want?	A. Small B. Medium C. Large	**B**

Clip 2 (18 seconds) – Making plans

Audio script: "Hey, are you free on Saturday? There's a new movie playing at the cinema. Want to catch the 7 PM show?"

Question	Answer choices	Correct answer
1. Where are they going?	A. Restaurant B. Cinema C. Park	**B**
2. What time will they meet?	A. 6:00 PM B. 6:30 PM C. 7:00 PM	**C**

Clip 3 (25 seconds) – Asking for directions

Audio script: "Excuse me, I'm looking for the nearest pharmacy. Is it far from here? I think I'm lost. Can you point me in the right direction?"

Question	Answer choices	Correct answer
1. Where is the person trying to go?	A. Museum B. Library C. Pharmacy	**C**
2. What is the person's problem?	A. They are lost B. They are late C. They are tired	**A**

Clip 4 (20 seconds) – Giving a compliment

Audio script: "Wow, I love your jacket! Where did you get it? That color really suits you. You have great style."

Question	Answer choices	Correct answer
1. What is the compliment about?	A. Hair B. Jacket C. Shoes	**B**
2. What does the speaker say about the color?	A. It's too bright B. It suits the person C. It's boring	**B**

Clip 5 (20 seconds) – Reacting to news

Audio script: "Guess what? I got the job! I can't believe it. I'm so excited. Let's go celebrate tonight!"

Question	Answer choices	Correct answer
1. What is the news?	A. Got a job B. Won a prize C. Moved to a new city	**A**
2. How does the speaker feel?	A. Sad B. Worried C. Excited	**C**

Answer Key:

Clip	Question 1	Question 2
1	B	B
2	B	C
3	C	A
4	B	B
5	A	C

Scoring: 1 point per correct answer = 10 points total.

Appendix C: Speaking Test Rubric

Instructions for rater: Listen to each student's recorded response (30-60 seconds). Rate each criterion on a scale of

Speaking Assessment Rubric

Criteria	Score 1 (Weak)	Score 2 (Fair)	Score 3 (Good)	Score 4 (Excellent)
Fluency (flow, speed, pauses)	Many long pauses; cannot complete sentences; very slow	Some pauses; short, simple sentences	Few pauses; speaks in short paragraphs; natural speed	Natural flow; no unnatural pauses; appropriate speed
Pronunciation (sounds, stress, intonation)	Difficult to understand; many errors	Some errors; mostly understandable	Few errors; clear pronunciation; some natural intonation	Near-native; natural rhythm and intonation; uses reductions naturally
Vocabulary (word choice, range)	Very basic; repetitive; frequent word searches	Adequate for basic needs; some repetition	Good range; some colloquial expressions; appropriate word choice	Rich vocabulary; natural use of slang/reductions; precise word choice
Comprehensibility (ease of understanding)	Listener struggles to understand meaning	Listener understands most, with some effort	Listener understands easily, with minimal effort	Listener understands effortlessly, like a native speaker

Scoring Guide:

Total score (out of 16)	Converted score (out of 10)
16	10.0
15	9.4
14	8.8
13	8.1
12	7.5
11	6.9
10	6.3

Total score (out of 16)	Converted score (out of 10)
9	5.6
8	5.0
7	4.4
6	3.8
5	3.1
4	2.5

Sample Picture Prompts (one per student, randomly assigned):

Prompt	Description
Prompt 1	*"You are at a café. The waiter brings you the wrong drink. You ordered a latte, but they gave you black coffee. What do you say to the waiter?"*
Prompt 2	*"You meet a friend you haven't seen for a year. Start a short conversation. What do you say?"*
Prompt 3	*"A foreign tourist asks you for directions to the nearest bus station. Help them. What do you say?"*
Prompt 4	*"Your friend tells you they just won a scholarship to study abroad. How do you react? What do you say?"*
Prompt 5	*"You want to return a shirt you bought because it's too small. What do you say to the store clerk?"*

Appendix D: Questionnaire (Pre-intervention and Post-intervention)

Instructions: Please circle the number that best represents your agreement with each statement.

Scale: 1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly Agree

Section A: Speaking Confidence (8 items)

Item	Statement	1	2	3	4	5
C1	I feel confident speaking English in real-life situations.	1	2	3	4	5
C2	I can order food in English without feeling nervous.	1	2	3	4	5
C3	I feel comfortable making small talk in English.	1	2	3	4	5
C4	I can ask for directions in English if needed.	1	2	3	4	5
C5	I believe my English pronunciation is clear.	1	2	3	4	5
C6	I can understand native speakers in short videos.	1	2	3	4	5
C7	I am proud of my English speaking ability.	1	2	3	4	5
C8	I think I can handle unexpected conversations in English.	1	2	3	4	5

Section B: Speaking Anxiety (7 items)

Item	Statement					
A1	I feel anxious when I have to speak English without preparation.	1	2	3	4	5
A2	I worry about making mistakes when speaking English.	1	2	3	4	5
A3	My heart beats fast when I am called on to speak English.	1	2	3	4	5
A4	I feel nervous recording myself speaking English.	1	2	3	4	5
A5	I am afraid that others will laugh at my English.	1	2	3	4	5
A6	I feel shy speaking English in front of classmates.	1	2	3	4	5
A7	I freeze when I have to speak English spontaneously.	1	2	3	4	5

Section C: Willingness to Communicate – WTC (5 items)

Item	Statement	1	2	3	4	5
W1	I am willing to speak English with a foreign tourist.	1	2	3	4	5
W2	I would start a conversation in English if someone spoke to me first.	1	2	3	4	5
W3	I am willing to order food in English at a restaurant.	1	2	3	4	5

Item	Statement	1	2	3	4	5
W4	I would volunteer to speak English in class activities.	1	2	3	4	5
W5	I would like to use short-form videos in future English classes.	1	2	3	4	5

Section D: Demographic Information

Gender: _____ Male _____ Female

Age: _____ years old

How many years have you studied English? _____ years

On average, how many minutes do you spend on TikTok/Reels each day? _____ minutes

Have you used TikTok/Reels for English learning before this course?

_____ Yes _____ No

Vietnamese Version (for students who prefer Vietnamese)

Hướng dẫn: Khoanh tròn số thể hiện mức độ đồng ý của em với mỗi câu.

Thang điểm: 1 = Hoàn toàn không đồng ý, 2 = Không đồng ý, 3 = Trung lập, 4 = Đồng ý, 5 = Hoàn toàn đồng ý

Phần A: Sự tự tin khi nói tiếng Anh (8 câu)

C1	Nội dung					
C1	Em tự tin khi nói tiếng Anh trong tình huống thực tế.	1	2	3	4	5
C2	Em có thể gọi món bằng tiếng Anh mà không lo lắng.	1	2	3	4	5
C3	Em thoải mái khi nói chuyện xã giao bằng tiếng Anh.	1	2	3	4	5
C4	Em có thể hỏi đường bằng tiếng Anh nếu cần.	1	2	3	4	5
C5	Em nghĩ phát âm tiếng Anh của em rõ ràng.	1	2	3	4	5
C6	Em hiểu người bản xứ nói trong video ngắn.	1	2	3	4	5
C7	Em tự hào về khả năng nói tiếng Anh của mình.	1	2	3	4	5
C8	Em nghĩ em có thể xử lý hội thoại bất ngờ bằng tiếng Anh.	1	2	3	4	5

Phần B: Lo lắng khi nói tiếng Anh (7 câu)

Câu	Nội dung					
A1	Em lo lắng khi phải nói tiếng Anh không chuẩn bị trước.	1	2	3	4	5
A2	Em sợ mắc lỗi khi nói tiếng Anh.	1	2	3	4	5
A3	Tim em đập nhanh khi được gọi nói tiếng Anh.	1	2	3	4	5

A4	Em hồi hộp khi tự quay video nói tiếng Anh.	1	2	3	4	5
A5	Em sợ người khác cười nhạo tiếng Anh của em.	1	2	3	4	5
A6	Em ngại nói tiếng Anh trước các bạn trong lớp.	1	2	3	4	5
A7	Em bị đứng hình khi phải nói tiếng Anh tự phát.	1	2	3	4	5

Phần C: Sự sẵn sàng giao tiếp (5 câu)

Câu	Nội dung					
W1	Em sẵn sàng nói tiếng Anh với khách du lịch nước ngoài.	1	2	3	4	5
W2	Em sẽ bắt chuyện bằng tiếng Anh nếu ai đó nói với em trước.	1	2	3	4	5
W3	Em sẵn sàng gọi món bằng tiếng Anh tại nhà hàng.	1	2	3	4	5
W4	Em sẽ tình nguyện nói tiếng Anh trong các hoạt động trên lớp.	1	2	3	4	5
W5	Em muốn sử dụng video ngắn trong các lớp tiếng Anh sau này.	1	2	3	4	5

Appendix E: Focus Group Interview Protocol

Purpose: To understand students' perceptions of the short-form video intervention

Duration: 20-30 minutes per group

Participants: 5-7 students per group (purposively sampled by proficiency level)

Language: Vietnamese (to ensure comfort and rich responses)

Recording: Audio recorded with permission, transcribed, then translated to English

Opening (5 minutes):

"Cảm ơn các em đã tham gia buổi phỏng vấn này. Cô muốn hỏi các em về trải nghiệm của các em khi học tiếng Anh bằng video TikTok/Reels trong 8 tuần qua. Không có câu trả lời đúng hay sai. Các em cứ thoải mái chia sẻ suy nghĩ thật của mình. Tất cả câu trả lời sẽ được giữ bí mật."

(Translation: "Thank you for joining this interview. I want to ask about your experience learning English with TikTok/Reels videos over the past 8 weeks. There are no right or wrong answers. Please feel free to share your honest thoughts. All responses will be kept confidential.")

Warm-up questions (5 minutes):

#	Question (Vietnamese)	Question (English translation)
1	Các em có thường xuyên xem TikTok/Reels không? Mỗi ngày xem bao nhiêu phút?	Do you watch TikTok/Reels regularly? How many minutes per day?
2	Trước khóa học này, các em đã từng dùng TikTok để học tiếng Anh chưa?	Before this course, had you ever used TikTok to learn English?

Main questions (15 minutes):

#	Question (Vietnamese)	Question (English translation)	Purpose
3	Các em thích hoặc không thích điều gì khi học bằng video TikTok/Reels trong lớp?	What did you like or dislike about learning with TikTok/Reels videos in class?	Overall perception
4	Những video này có giúp các em hiểu tiếng Anh thực tế tốt hơn không? Tại sao có hoặc không?	Did these videos help you understand real English better? Why or why not?	Authenticity

#	Question (Vietnamese)	Question (English translation)	Purpose
5	Phần nào trong buổi học các em thấy hữu ích nhất? (xem video, shadowing, đóng vai, hay tự quay video?)	Which part of the lesson did you find most useful? (watching videos, shadowing, role-play, or creating your own videos?)	Identify effective techniques
6	Việc tự quay video có khiến các em lo lắng không? Tại sao? Có thay đổi gì theo thời gian không?	Did creating your own videos make you nervous? Why? Did it change over time?	Anxiety over time
7	Sau 8 tuần, các em có thấy tự tin hơn khi nói tiếng Anh không?	After 8 weeks, do you feel more confident speaking English?	Confidence change
8	Các em có muốn áp dụng phương pháp này cho các khóa học sau không? Tại sao?	Would you recommend this method for future courses? Why?	Sustainability

Closing questions (5 minutes):

#	Question (Vietnamese)	Question (English translation)
9	Các em có góp ý gì để cải thiện khóa học này không?	Do you have any suggestions to improve this course?
10	Có điều gì khác các em muốn chia sẻ về trải nghiệm của mình không?	Is there anything else you would like to share about your experience?

Closing script (Vietnamese):

"Cảm ơn các em rất nhiều vì đã chia sẻ. Những ý kiến của các em sẽ giúp cô cải thiện khóa học và cũng sẽ được sử dụng trong nghiên cứu này. Mọi thông tin đều được bảo mật. Chúc các em học tốt!"

(Translation: "Thank you very much for sharing. Your opinions will help me improve the course and will be used in this research. All information is confidential. Good luck with your studies!")

Appendix F: Raw Data Tables

Table F1: Listening Test Scores – Raw Data (n = 22)

Student ID	Gender	Pre-test	Post-test	Change (+/-)

#54 Enhancing English Syntactic Competence through AI-Supported Instruction: A Quasi-Experimental Study of English-Majored Sophomores at HUFLIT

Myphuongnguyen[1]

Abstract

The aim of the present study was to assess the effectiveness of artificial intelligence (AI) in improving HUFLIT English-majored sophomores' syntactic skills with the core textbook "Analyzing Sentences: An Introduction to English Syntax" by Burton-Roberts, N. (2021) . In consideration of the scarcity of research on the application of AI in Syntax subject, a quasi-experimental mixed-methods approach was employed. A total of 80 second-year students majoring in English at HUFLIT University were randomly selected.

The methods used for collecting the data included a pretest, a posttest, a perception questionnaire, and semi-structured interviews. The experimental group used AI tools, including ChatGPT, NotebookLM, and Edtechcorner.com with Text2Tree to support learning and practice. Quantitative findings show that the experimental group significantly outperformed the control group on three aspects of syntactic ability: conceptual understanding, applied knowledge, and structural analysis, and large effect sizes were recorded.

The findings showed large effect sizes for these three aspects. The qualitative findings indicated that AI technology made learners more autonomous and motivated. However, there were limitations such as dependence and inaccuracies.

The results imply that AI can potentially serve as a pedagogical scaffold in the teaching of the Syntax subject. This study adds to the body of research on AI in assisting language learning by expanding its scope to another underexplored area of language acquisition and providing implications for the integration of AI in higher education settings. Briefly, AI provides valuable tools for teaching learners' syntactic competence effectively.

***Keywords*:** artificial intelligence, syntactic competence, AI-supported instruction, higher education pedagogy

1. Introduction

The rapid integration of artificial intelligence (AI) is currently changing the paradigm of higher education. Regarding the Teaching English to Speakers of Other Languages (TESOL) program, the potential of AI has already been well researched concerning its ability to improve communicative macro-skills, yet its applicability within formal linguistic studies, particularly English syntax – remains uncharted territory. For sophomore students majoring in English, the process of learning language mechanics becomes a mentally demanding task, entailing a move from instinctive to systematic language behavior.

1.1 The Problems of Teaching Syntax

[1] *Master of TESOL, English, Foreign Language Faculty, HO CHI MINH CITY UNIVERSITY OF FOREIGN LANGUAGES AND INFORMATION TECHNOLOGY, Ho Chi Minh City, Viet Nam*

The syntax curriculum of Ho Chi Minh University of Foreign Languages-Information Technology is built based on the syntax curriculum of Burton-Roberts, N. (2021). This model requires students to understand X-bar Theory, Hierarchical Phrase Structure Markers, and Constituent Analysis. Historically, the teaching of these theoretical aspects of linguistics takes place in a deductive manner. As a result, students may experience linguistic fossilization or become overwhelmed with anxiety because of their inability to conceptualize the relationships between various elements on a deep structure level.

1.2 AI as a Cognitive and Visual Scaffold

Considering this matter, the arrival of LLMs in conjunction with EdTech technologies provides a wonderful chance to do so. The mentioned combination of ChatGPT and NotebookLM, along with solution-oriented tools like Text2Tree, builds interactive scaffolds for students. Technology offers experiments with creating trees, which leads to getting immediate feedback, unlike traditional textbooks. AI technology helps make syntax more engaging.

1.3 The Research Gap

Even though there is a lot of empirical evidence supporting the use of AI in general English language learning, there is still a lack of literature addressing its effectiveness in acquiring theoretical knowledge about the syntax of the language. Most studies deal either with the use of AI in acquiring lexicon or improving stylistics; there is little knowledge about the role of AI in the process of forming concepts, knowledge, and structural analysis.

To fill this gap, the current study applies a quasi-experimental mixed-method approach, which aims to measure the effect of using artificial intelligence on syntactical skills. The sample includes 80 English major sophomores studying at HUFLIT. This study analyzes both quantitative indicators of syntactical competence improvement and qualitative ones related to the growth of autonomous and motivated behavior among students.

1.4 Research Questions

To achieve the objectives of the study, the following research questions are proposed:

1. To what extent does AI-supported instruction improve English syntactic competence among English-majored sophomores at HUFLIT compared to traditional instruction?

2. How does the application of AI-assisted instruction affect the students' skills in analyzing English Syntax, such as the identification of sentence constituents and the building of phrase structures?

3. How do students discern the usefulness and applicability of AI-assisted English syntax study tools?

2. Literature Review

2.1. Theoretical Foundations of Syntactic Competence

2.1.1. Syntactic Competence and the Role of AI in EFL Education

Syntax remains one of the important aspects of language proficiency, which is mostly about formulating grammatically accurate sentences. According to contemporary SLA studies, the syntax can no longer be defined as the linear order of words. Instead, the term denotes the hierarchical structure of constituents following specific internal rules. The definition correlates with the understanding of language in terms of cognitive and generative linguistics as a rule-governed system in the mind (Ellis, R. (2006); VanPatten, B. (2004)). However, despite being

crucial for language competence, syntax is often called the hardest part of teaching English as a foreign language due to its abstract nature.

2.1.2. The Problem with Hierarchical Processing

Analytically, syntactic competence is knowledge of dimensions such as constituency, grammatical category, and grammatical function. This requires that learners move beyond surface-level pattern recognition and achieve structural understanding. According to VanPatten (2004), many students have challenges shifting from linear processing to hierarchical processing and, instead, depend on shallow features for comprehension purposes. Factors related to cognition and memory exacerbated this challenge. Therefore, the idea of Cognitive Load (Sweller, J., Ayres, P., & Kalyuga, S. (2011)) is crucial; if the structural complexity is higher than processing capability, learning becomes problematic.

2.1.3. Integrating Structure and Communication

However, it is important to note that syntactic competence should not be considered separately from communicative competence. Though earlier models distinguished between competence and performance, later models underscore that “grammatical competence” forms the basis for communication (Canale, M. (1980)). There exists empirical evidence suggesting that the higher the level of grammatical sophistication, the more proficient students become at producing speech and texts. In most cases, however, in EFL contexts, teachers prefer mechanical drills rather than grammatical explanations**.**

2.1.4. The Catalyst of Generative AI

Technical breakthroughs, such as generative artificial intelligence technologies, for example, ChatGPT, can provide the necessary ways to handle the highlighted challenges. While conventional TELL was focused on interaction and autonomy (Chapelle, C. A. (2001)), new opportunities arise with AI for personalization and cognitive engagement (Zawacki-Richter, O. et al., (2019), Sain, Z. H. et al., (2024)).

Among the most important features that need to be highlighted is the ability of AI to offer real-time feedback, which is crucial for making students "notice" certain linguistic features (Nassaji, H., & Kartchava, E. (Eds.). (2017)). At the same time, AI enables self-directed learning and allows teachers to customize the curriculum to meet the learners' needs (Sain, Z. H., et al., 2023).

2.1.5. Limitations and Gaps in Research

Such opportunities also bring risks when it comes to using AI. Misconceptions or “hallucinations” might arise from AI-generated data, and the trustworthiness of AI in formal structural analysis is still under question (Sain, Z. H. et al., 2023). Moreover, successful integration depends on pedagogical literacy, which can easily lead to passive and overly reliant learners on automation.

Finally, while there is a growing body of research on AI and general language abilities (vocabulary, writing, speaking), there is a serious lack of studies on syntax acquisition. Only a few quasi-experimental studies have examined the precise effect of AI-driven training on the development of syntactic competence, leaving a large gap for future empirical study.

2.2. Syntactic Competence in EFL Settings

Syntax is essential in the language but is frequently poorly taught in many EFL environments where traditional teaching approaches are used. Explicit instruction enhances

declarative knowledge, but it rarely transfers to procedural performance (Ellis, R. 2006). This gap contributes to explain why learners often generate simpler texts, with fundamental coordination rather than complicated hierarchization, such as subordination or embedding (Lu, X. 2011).

Recent frameworks reconceptualize syntactic competence as a multidimensional construct of complexity, accuracy and fluency (CAF), rather than simply the control of individual rules (Bulté, B., & Housen, A. (2012)). Research has shown that combining grammar education with communicative utility (Norris, J. M., & Ortega, L. (2000)) and high-frequency, interactive input (Ellis, N. C. (2002)) is essential for its success. These problems are much more apparent in places like Vietnam, where testing matters. Testing students on isolated themes and forcing them to learn things by heart does not help them to develop actual advanced language abilities.

2.3. The Challenges of Syntax Teaching and Learning

Syntax can be quite difficult to understand because of its abstract and hierarchical character. Learning syntax is different from lexical acquisition in that it comprises the establishment of unobservable structural linkages in the minds of the learners, imposing a significant cognitive load on working memory (Sweller, J. (2019)). This load is especially evident in input-poor contexts when learners do not have enough exposure to reinforce these sophisticated mental models.

The main problem is that L2 learners often rely on linear processing methods. Students concentrate on surface features like word order and do not understand the hierarchy underlying the information (Ellis, R. 2006). Therefore, L2 writing is marked by the absence of syntactic diversity, and learners tend to generate simplified sentences and avoid sophisticated syntactic structures, such as subordination and embedding (Lu, X. 2011).

Traditional pedagogies that emphasized isolated explanations and repetitious exercises tended to worsen such difficulties. Meta-analytic evidence reveals that such strategies are only effective when paired with meaningful communication (Norris, J. M., & Ortega, L. 2000). While technology-mediated environments provide important opportunities for engagement, feedback and various exposures (Ellis, N.C. (2002)), they do not necessarily eliminate the basic cognitive demands of syntactic processing.

2.4. Artificial Intelligence in Syntax Learning

One of the greatest benefits of AI is that it can provide instant and accurate feedback. Traditional classroom feedback is often delayed, while AI can spot syntactic problems in real time. This immediacy fosters “noticing” (a cognitive state important for internalizing language’s non-observable hierarchical patterns) (Heift, T., & Schulze, M. (2012)). The application of Artificial Intelligence (AI) in language teaching offers a revolutionary method of solving the intangible problems of syntactic acquisition. Unlike conventional training, AI-mediated training creates an interactive data-driven environment that supports complex mental mapping with personalized scaffolding, a basic tenet of usage-based acquisition theories (Ellis, N. C. (2002)). AI is also a useful tool for visualizing the structure of phrases. AI allows the learner to produce and manipulate phrase markers (tree diagrams), leading the learner step-by-step to identify constituents and label phrases. It can also help minimize the cognitive load of abstract structural analysis.

Moreover, AI also facilitates autonomous and self-regulated learning by allowing students to verify their theories of language through continuous interaction. Recent studies

suggest that AI-enabled environments help with personalization and student engagement (Chang, W.-L., & Sun, J. C.-Y, 2024; Peña-Acuña, B., & Durão, R. C. F. (2024)) . However, there are limitations in reference to AI's capacity to handle deep recursion and complicated hierarchy. Therefore, AI should be used as a tactical scaffold rather than a complete substitute for pedagogical oversight to avoid surface learning.

2.5. Research Gap

Although there is much research on the impact of AI-aided language acquisition, it is important to clarify how far these developments contribute to the evolution of syntax as a hierarchical system. Recent meta-analyses (Kim, J. H., (2004); Torres, P. J., & Kahveci, Y. E., (2025)) have often confirmed positive benefits of AI-based therapies on general competency (in particular vocabulary and writing), but specific research on syntactic advances is limited, rather than cognitive processes driving syntactic translation. There is a gap between AI applications and formal linguistic theory. Finally, yet another concern is the dearth of quasi-experimental studies on English majors in the Southeast Asian environment, such as Vietnam. This project aims to fill these gaps by examining the contribution of AI-supported instruction to the deep syntactic competency of HUFLIT sophomores.

2.6 Implications for Syntax Pedagogy

TELE's second disruption is to use artificial intelligence to teach students the rules of grammar. These technologies promote engagement and cognitive scaffolding in real-time environments, where learners can receive immediate feedback on tough language challenges (Egwim, O. E., & Aloyo, M. (2026)). Such automated algorithms can be used to uncover defects to learn the grammar rules and improve the writing skills (Kim, J. H. (2004)).

However, artificial intelligence learning works when the design of education and teacher involvement is proper. The learners may focus on correcting surface-level errors rather than making more profound structural changes in the absence of a clear instructional framework, which results in a greater cognitive burden (Egwim, O. E., & Aloyo, M. (2026)). Furthermore, AI is highly adept at identifying grammar but may not always be able to capture the nuance needed to analyze content (Egwim, O. E., & Aloyo, M. (2026)). Thus, the teacher's role is indispensable in evaluating the feedback provided by AI and guiding learners to reach both theoretical accuracy and functional syntactic competence (Egwim, O. E., & Aloyo, M. (2026); Kim, J. H. (2004)).

3. Methodology

3.1. Research Design

This study adopts a quasi-experimental mixed-methods design to explore the effects of artificial intelligence (AI) tools on the syntactic competency of sophomore English major students at HUFLIT University. The methodology permitted both quantitative and qualitative analysis of the effects of AI-supported learning on learners' Conceptual Understanding (theoretical understanding), Applied Knowledge (function labeling), and Structure (creating X-bar tree diagrams).

Pre- and post-intervention test results with students' reflections and interviews are merged to provide a detailed understanding of the instructional benefits of AI in Syntax education. The selection of the quasi-experimental method was driven by its efficiency and suitability in the context of real-life education, especially when random assignments are impractical. As pointed out by Dörnyei, Z. (2007), quasi-experiments have proven to be quite advantageous in conducting studies in classrooms since they can compare while

accommodating the limitations of the organizational setting. In this study, two Syntax classes were divided into control and experimental groups, thereby reducing disruption to the current curriculum while maintaining comparability.

3.2. Context and Participants

This study was conducted at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), and particularly in its English Department. 80 sophomore students participated, divided equally into the control and experimental groups, each having 40 students, respectively. All the participants in the experiment had the same level of English skills as confirmed by their placement tests.

In contrast to the control group, where conventional teaching techniques such as teacher feedback and task completion from the textbook were used, the experimental group learned through the integration of the same curriculum and AI-integrated technology tools, including ChatGPT (for getting immediate feedback iteratively on constituent analysis), NotebookLM (mind maps, infographics, and quiz contents of the core textbook), and Text2Tree (Edtechcorner.com) (for making hierarchies of structures and phrase markers). This achievement was made possible by introducing students to all the mentioned AI tools within one week of beginning the lessons.

Both groups followed the same core textbook, "Analyzing Sentence: An Introduction to English Syntax" (Burton-Roberts, N. (2021)). Both groups were taught by the same instructor.

3.3. Instruments

To evaluate the effectiveness of the intervention, different tools and techniques were utilized to provide an overall evaluation of the effectiveness of the intervention Conceptual Understanding (theoretical comprehension), Applied Knowledge (function):

a. Syntactic competency tests: consist of a pretest and a posttest in three domains:conceptual understanding, applied knowledge,and phrase marker (structures). All the questions are based on the pedagogical model of Analyzing Sentences by Burton-Roberts, N. (2021). The reliability of the test was determined using the Cronbach's Alpha measure, and the result was 0.89.

b. Questionnaire for Perception: A tool that measures motivation, autonomy, and usability using a 5-point Likert scale from "1 – Strongly Disagree" to "5 – Strongly Agree". Apart from this, certain open-ended questions were also asked. The questionnaire was distributed through the internet following the intervention to assess the extent of engagement among students along with their perception regarding learning using AI. This questionnaire was designed based on existing measurement tools related to student engagement, which comprised of the following three aspects: Behavioral Engagement (participation, effort), Cognitive Engagement (commitment towards learning, strategic use**),** Emotional Engagement (interest, enjoyment, attitudes).

c. Semi-Structured Interview: A randomly selected set of 10 students (experimental group) were interviewed at the end of the class to learn more about their experiences with cognitive offloading during this time.

3.4. Procedure

The research extended for twelve weeks, corresponding to the typical academic term. During the first week, the two groups took part in a pre-test conducted in an experimental

setting. On the other hand, members of the experimental group underwent orientation on AI technology during the first week.

Weeks two to eleven involved the two groups undergoing the same syllabus on Analyzing Sentences: An Introduction to English Syntax (Burton-Roberts, N. (2021)).

The primary distinction was in Syntax practice. The control group did their tasks manually, got extra practice through conventional worksheets and feedback from teachers (without AI) supervised by the instructor, whereas the experimental group performed similar tasks with the help of AI-based platforms. To solve the problem of AI analysis contrary to the curriculum of Burton-Roberts, a framework of the CREATE query was introduced (Character, Request, Examples, Adjustments, Type, and Extras). The experimental group were guided to set the AI's role as a linguistics expert proficient in the 5th edition of Burton-Roberts. They utilized ChatGPT as an instant "tutor" in class to get an instant formative feedback system from AI. A completely new teaching method has been used to replace drawing X bar tree-diagrams on paper by using Text2Tree (EdTech Corner.com). Students will work in groups to draw and label phrase markers (tree- diagram) based on report titles. NotebookLM was used for mind maps, infographic, summarizing the structures of the core text book, creating quizzes to review the contents of the chapters. Participants in the experimental group were prompted to make use of these tools both during classroom activities and while studying independently. Each week, they responded to reflection questions to evaluate their learning progress and their engagement with the AI tools. To facilitate the seamless integration of AI into the learners' study process, instructors made sure that the tools were used correctly while imposing few limitations. The final week of the study was dedicated to carrying out post-testing, interviewing, and completion of the online survey by all participants.

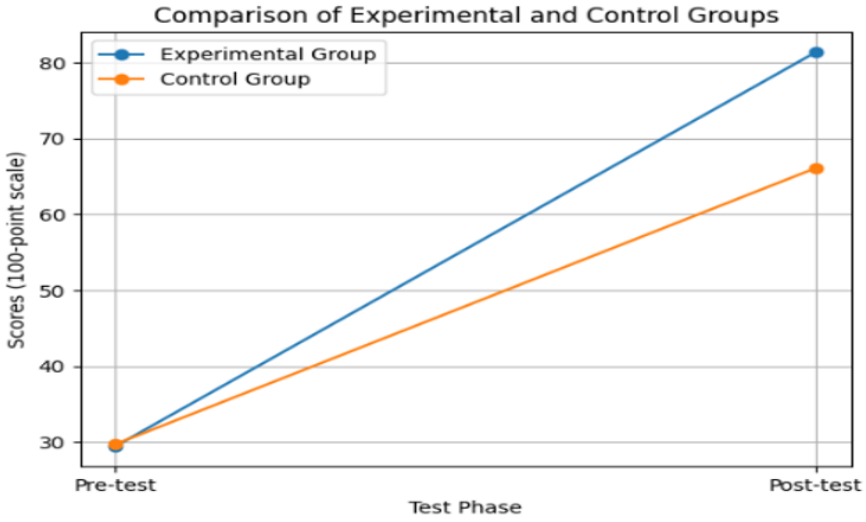
3.5. Data Analysis

Quantitative data from pre- and post-tests were analyzed using paired-sample t-tests to identify within-group gains and independent-sample t-tests to detect between-group differences. Effect sizes were calculated using Cohen's d to interpret the practical significance of the findings. Statistical analysis was carried out using SPSS version 26 (IBM Corp., 2019). The qualitative data were anlyzed using MAXQDA software. To allow categories and patterns to emerge naturally from the data, coding was done inductively. Themes such as "confidence growth," "feedback appreciation" and "AI-related challenges" were identified and compared with the instructor's observational notes to ensure reliability.

4. Results

The statistical data indicated significant improvement in the level of syntactic competence in the experimental group relative to the control group. The use of AI's instant feedback feature along with visualization features in the software led to a big jump in the performance rate.

4.1 Effectiveness of Academic Competence



Both groups started with low initial competencies, since it is common for students to find it challenging to begin studying syntax. However, after 12 weeks, there was significant progress in the experimental group.

Table 1

Comparison of Score Results between EG and CG (100-point scale)

Statistical Index	Experimental	Control	p	Cohen's d
Average Pre-test	29.44 (SD=7.21)	29.72 (SD=7.47)	> .05 (n.s.)	0.04
Average Post-test	81.39 (SD=4.39)	66.11 (SD=3.01)	< 0.001	4.06
Average Increase	+51.95	36.39	< .001	

Figure 1 Comparison of Experimental and Control Groups

4.1.1. Baseline Equivalence (Pre-test Analysis)

Before the introduction of the pedagogical intervention, the experimental group and the control group exhibited almost the same baseline proficiency in English language. The experimental group obtained an average score of 29.44 (SD = 7.21), and the control group obtained an average score of 29.72 (SD = 7.47). The high p-value obtained (p > .05) proves that there was no statistical significance between the two scores above, although the very small effect size obtained (d = 0.04) proves their total similarity.

4.1.2. Post-test Evaluation and Pedagogical Impact

There were improvements made for both the control group and the experimental group during the experiment period. However, there was a very significant difference seen between the two groups with respect to performance. The Experimental Group had a mean score of 81.39 (SD = 4.39), which showed a very high mean difference of +51.95. The Control Group had a mean score of 66.11 (SD = 3.01), which demonstrated a low mean difference of +36.39.

The Independent Samples t-test shows that this difference is highly significant (p < .001)

4.1.3. Interpretation of Effect Size

The most convincing result for language instructors would be the Cohen's d calculation which yielded 4.06. In any research on education, an effect size of 0.80 is considered significant. Effect size of 4.06 is indicative of an immensely profound effect on teaching and learning.

As far as reality is concerned, the mean of the experimental group is four standard deviations higher compared to that of the control group. This clearly shows that the novel method, tool or framework used in the experimental group surpasses the conventional methods employed in the control group, thus providing clear guidance for future curriculum development in TESOL contexts.

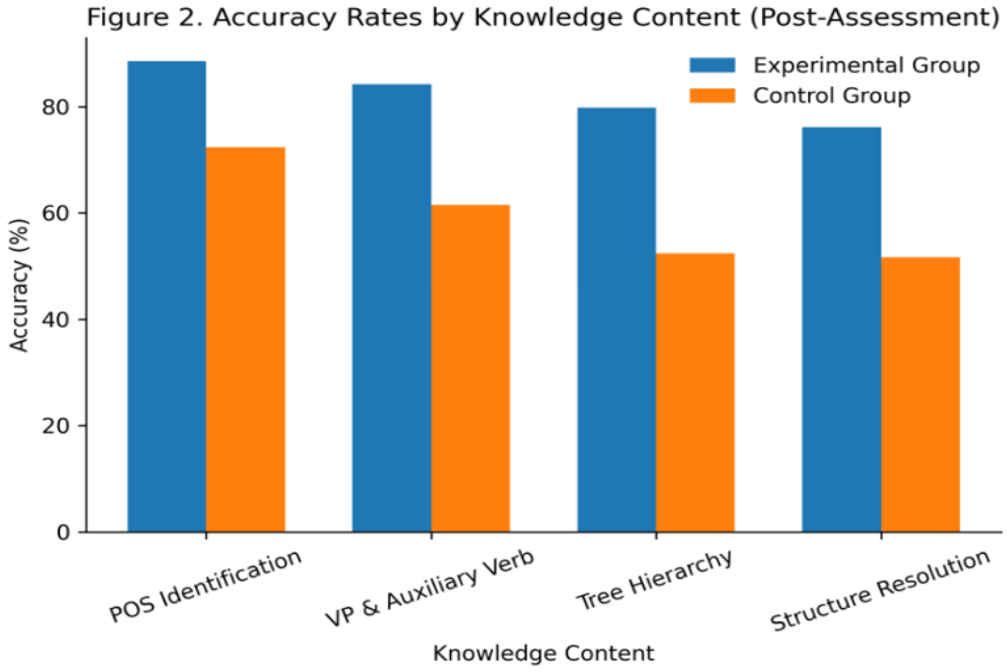


Table 2

Accuracy Rate by Knowledge Content (Post-Assessment)

Content Knowledge	Experimental Group	Control Group	Performance gap
Part of Speech Identification(POS)	88.5%	72.3%	16.2%
Verb Phrase & Auxiliary Analysis	84.2%	61.5%	22.7%
Tree Hierarchy	**79.8%**	**52.4%**	**27.4%**
Structure Resolution	**76.1%**	51.6%	24.5%

The most significant improvement (+27.4%) was in the "Tree Hierarchy" skill. Thanks to Edtech corner.com, Experimental group students were able to flexibly adjust nodes and branches, helping them better understand the dominant and sister relationships in the X-bar structure. Students were 76.1% accurate on the “Structural Ambiguity Resolution” task —they understood how the same words arranged differently mean different things.

Figure 2. Accuracy Rates by Knowledge Content (Post-Assessment)

4.2. Qualitative Results

Analysis of surveys and interviews demonstrated consistent items that confirm the quantitative results:

4.2.1 Section 2: Behavioral Engagement

Table 3

Behavioral Engagement in AI-supported Learning

Item	Statement	Mean Score	Interpretation
Q1	Active participation	4.25	High
Q2	Task Completion	4.07	High
Q3	Time-on-task (AI & Traditional)	3.99	Moderate-High
Q4	Instruction Compliance	4.34	High
Q5	Extra Exploration	4.29	High
Total	**Overall Behavioral Engagement**	**4.19**	**High**

Behavioral Engagement has been greatly improved by AI techniques. The mean value for this dimension was 4.19, which means that the student was quite active in the course.

One of the significant results of the utilization of AI technology is students' attentiveness in finishing assignments (M = 4.07) and desire to dig into detail regarding the subject beyond class hours (M = 4.29). The results reveal that learners perform better in practice with the help of AI technology (M = 3.99).

4.2.2. Section 3: Cognitive Engagement

Table 4

Summary of Overall Cognitive Engagement

Item	Statement	Mean Score	Interpretation
Q6	Strategic Understanding	4.28	High
Q7	Knowledge Integration	4.25	High
Q8	Self- Monitoring	4.07	High
Q9	Problem-Solving	4.19	High
Q10	Feedback Application	4.09	High
Total	**Overal Cognitive Engagement**	**4.18**	**High**

An in-depth examination of the Cognitive Engagement ratings clearly indicates that an AI-based teaching technique ensured that the learning process had depth rather than being superficial. The fact that the average rating of all four items is 4.18 points leads to the conclusion that significant cognitive effort has been exerted.

If AI-assisted exercises are related to students' previous knowledge, one can note the presence of a noticeable trend (M = 4.25), as well as a high degree of tolerance for challenges when faced with difficult situations (M = 4.19). As far as TESOL instructors are concerned, the results indicate that AI technologies may be utilized during syntax instruction and regarded as "cognitive tools" for students, who are expected to reflect upon their understanding (M = 4.07) and use feedback correctly (M = 4.09).

4.2.3. Section 4: Emotional Engagement

Table 5

Emotional Engagement and Learner Motivation

Item	Statement	Mean Score	Interpretation
Q11	Enjoyment of use	4.38	Very High
Q12	Excitement for activities	4.21	high
Q13	Interest in subject matter	4.10	high
Q14	Increased interest in syntax	4.40	Very High
Q15	Satisfaction/Achievement	4.34	Very High
Total	**Overall Emotional Engagement**	**4.29**	**Very High**

The AI-supported learning environment appears to elicit a very positive emotional reaction in terms of emotional engagement. With an average score of 4.29, the students felt happy and satisfied. It is worth noting that the AI software was quite efficient in making the process of learning the English syntax enjoyable (M=4.40).

This made the learning process much easier for students because the subject was considered a difficult one. Moreover, the high degree of contentment related to the completion of tasks (M = 4.34) indicates that the immediacy of feedback from the AI contributes to emotional satisfaction, which promotes learning success.

4.2.4 Section 5: Perceived Usefulness (TAM)

Table 6

Summary of Perceived Usefulness

Item	Statement	Mean Score	Interpretation
Q16	Better Understanding	4.41	Very High
Q17	Improved Accuracy	4.32	Very High
Q18	Learning Efficiency	4.29	Very High
Q19	Helpful Feedback	4.35	Very High
Total	**Overall Perceived Usefulness**	**4.31**	**Very High**

Based on the results of the investigation conducted on the concept of PU, the students have a very positive view about the application of AI as facilitators for their learning objectives. On average, the mean score on this construct is 4.31 and is classified under the "Very High" level. Based on the data presented, the most prominent advantage of the incorporation of AI technology in the learning process would be the improvement of knowledge about syntax (M = 4.41) and feedback using AI (M = 4.35). As such, the application of AI technology is not considered simply a means but rather a necessity in achieving efficiency (M = 4.29) and accuracy (M = 4.32).

4.2.5 Section 6: Perceived Ease of Use (PEOU)

Table 7

Summary of Perceived Ease of Use (PEOU)

Item	Statement	Mean Score	Intepretation
Q20	AI tools are easy to use	4.13	High

Q21	I can use AI tools without much difficulty	4.09	High
Q22	It is easy to learn how to use AI tools for syntax learning.	4.19	High
Q23	I feel confident using AI tools independently.	4.15	High
Total	**Average Perceived Ease of Use**	**4.14**	**High**

Effectiveness of Syntax Learning with AI Assistance: As seen in Q22, the maximum mean score achieved was regarding the ease of learning the AI technology for syntax learning. In other words, the AI-based design had managed to reduce the amount of cognitive load usually imposed when learning about complicated syntactic rules, such as X-bar theory.

Operational Independence: The excellent results in Q23 (4.15) are an indication of a high degree of confidence among the participants. The quasi-experimental approach offered sufficient guidance to enable the students to move from guided instruction to independent AI practice seamlessly.

Lack of Technical Complexity: The minimum score (2.76) obtained in Q21 demonstrates that more than 81% of the students (32.4% agreed strongly while 48.5% were of the same opinion) found the technology user-friendly.

Considering the Technology Acceptance Model, a high level of PEOU is one of the key predictors of a person's PU as well as his/her intention to use the technology. The results indicate that since students found it easy to use the AI applications, they were more motivated to study the challenging English Syntax.

Cronbach's alpha test revealed that the perceived ease of use scale had excellent internal consistency since its value exceeded the minimum acceptable level of 0.70.

4.2.6 Section 7: Behavioral Intention

Table 8

Summary of Behavioral Intention

Item	Statement	Mean Score
Q24	Intention to continue use	4.32
Q25	Recommendation to others	4.35
Total	**Overall Behavioral Intention**	**4.34**

The impact of the students' Behavioral Intention (BI) was considered to determine whether they would like to use the technology further to perform tasks in class. There is a very high acceptance rate on the part of the respondents (M=4.34). Moreover, it should be noted that students are eager to continue using the tool to learn English syntax (M = 4.32), and they have been quite supportive regarding recommendation of the tool (M = 4.35). This particular result is especially important when comparing BI to the previously mentioned indicator, namely, Perceived Ease of Use (M = 4.14).The mean for BI has increased by several scores, indicating that benefits from using AI tools exceeded possible difficulties. Therefore, obtained high BI score is sufficient evidence of the acceptability of AI tools used to teach linguistic phenomena, such as X-bar theory, to sophomore students.

4.2.7 Section 8: Open-Ended Questions

Online questionnaires and interviews showed a very high level of acceptance among the students belonging to the experimental group, their average scores being 3.97 out of 5. They valued most their ability to lessen anxiety while studying a difficult subject like Syntax.

Table 9

Students' level of agreement on the dimensions of AI (EG)

Cognitive Dimension	Average Score (1-5)	Popular Interview Topics
Ease of Use	3.94	"Drawing trees using software is much more intuitive than drawing them by hand."
Promoting self-learning	3.86	"I can analyze sentences in daily news articles using AI."
Moral Awareness	3.88	"I know AI can create 'illusions,' so I always compare it to my textbook."
Utilities	4.22	"AI provides instant explanations when I'm in doubt about a schema node."

As shown in Table 9, the experimental group demonstrated a positive perception toward the cognitive aspects of using AI, except for the component of utility, which received the lowest mean score (M = 3.87). In contrast, utility was considered the most important aspect (M = 4.22), suggesting that students appreciated AI for offering real-time explanations in case they faced challenges in drawing syntactic trees. Thus, AI worked as a tool that facilitated students' problem-solving process and served as a cognitive scaffold. Another important cognitive component that scored rather highly was ease of use (M = 3.94). Students mentioned that digital drawing of trees is much easier than doing so by hand since it is a more convenient visual.

Nevertheless, self-learning (M=3.86) means that there is a moderately positive attitude, which implies that the respondents have taken advantage of AI technology to investigate real language data, for example, news headlines, independently. Therefore, the use of AI technology has encouraged self-regulated learning among the EFL learners outside the classroom environment. Finally, moral awareness (M=3.88) reveals that the respondents have critically reflected on the results produced by AI technology while being aware of potential issues, such as hallucinations, and verifying the data against appropriate materials used in their courses.

The results obtained from the interview showed that 77.78% of the participants rated their interest in the study of Syntax to be “high” and “very high.” The learning experience was described as “interactive and game-based,” which helped students overcome psychological barriers when abstracting language.

Briefly, in each category (Behavioral, Cognitive, Emotional Engagement, PU, PEOU, and BI), the evidence reflects a consistent level of "High to Very High" acceptance of the AI system. This provides a very compelling storyline for our study: not only does the system make learning simple (PEOU), it also engages learners when they learn difficult language theories (Engagement; PU).

5. Discussion

The success of the AI-assisted teaching system at HUFLIT is not just a matter of technology substitution but a fundamental change in both perception and pedagogy. In the preceding analysis, it can be stated that AI has an irreplaceable function in the process of scaffolding that bridges the gap between students' linguistic skills and reasoning capacities.

5.1 Offloading and Structural Focus

The most striking finding is the ability of AI to reduce the "extraneous cognitive load." However, the success of the model of AI-enabled teaching at HUFLIT represents not only a shift in technologies but also a major structural reorganization from the perspectives of cognition and pedagogics. The statistics prove that AI performs the important role of a "scaffolding system" that supports the shift from natural language competency to analytical competence.

5.2. Offload Mechanism and Emphasis on Logical Structure

Another important finding of this study is AI can discharge the offloading of "extraneous cognitive load." In traditional methods, students are often overwhelmed by having to both memorize rules for drawing binary branches and present diagrams proportionally on paper, leaving them with insufficient mental energy to contemplate the logic of the component relationships. The use of Edtechcorner.com allows students to perform "cognitive offloading" for surface presentation tasks, thereby focusing all resources on "germane load"—that is, building mental schemas of hierarchical structures and complement functions.

This does not detract from the process of critical thinking but encourages the concept of "Strategic Hybridization." The instant feedback that students get when working on the diagrams in a digital environment enables them to learn the syntax rules by getting engaged actively, rather than passively listening to lectures.

5.3 Overcoming Linguistic and Cultural Obstacles for Vietnamese Students

Positive correlations between students' self-confidence and use of AI ($r=0.46$, $p<0.01$) were observed. Thus, students who used the AI more often were more confident. Taking into account Vietnamese culture, where "face" matters, the importance of using AI to create a "low stakes" environment cannot be underestimated. The EG students were brave enough to try Wh-Movement type sentences or multi-NOM types of sentences without worrying about criticism by others.

In addition, the use of AI was quite advantageous in dealing with the problem caused by the "topic-comment" type of sentences in Vietnamese. The approach of using "movement tests" and "substitution tests" with verification by the AI was useful in making students change their thinking from equivalent translation to structure-based.

5.4. AI Competence and Prompt Engineering's Importance

One important takeaway from the experience is that the application of the tools alone is not sufficient. The success of the interventions largely depends on the students' AI competence and prompt engineering skills. Students well-trained in the "CRAFT" framework are better able to control AI, identifying when AI produces analyses that deviate from the 5th edition of Burton-Roberts.

The phenomenon of "AI hallucination" remains a significant pedagogical risk. LLM models sometimes produce parsings that sound reasonable but violate binary branching

principles or mislabel complementizers. Therefore, to maintain academic integrity in AI classrooms, students must be positioned as "critical testers" rather than "passive consumers."

5.5. Implications for the Development of the TPACK-AI Model

The research provides empirical evidence for the evolution of the TPACK model into "TPACK-AI." The interdependence between pedagogical knowledge, technology, and content is evident in the fact that instructors must master subtle changes in the 5th edition (such as the numeration of word numbers) to design prompts that allow the AI to accurately reflect these theoretical updates. In the process of implementation of the AI tool, there is no substitution for teachers; rather, their ability is augmented to give personalized and quality feedback to all the 80 learners, which was not possible before.

Secondly, it validates the TRAIT hypothesis, which holds that success depends on the extent to which the model generated by AI is influenced by skills and knowledge of a highly qualified human instructor. Without it, students are more likely to become overly reliant on technology.

6. Conclusion

Learning syntax through artificial intelligence (AI) technology can be considered a unique approach, which contributes to improving the overall academic results and motivational aspects for the students learning languages. Application of the technologies of artificial intelligence and syntax diagram software in the Burton-Roberts, N. (2021) educational model successfully solved the issue of low engagement and low-level analytical skills of sophomores.

6.1 Effectiveness of the Initiative

In terms of its effectiveness, the initiative has proven to be very effective in several ways:

Educational Results: The experimental class attained a mean score after evaluation of 81.39, which is a very remarkable change from their starting mark of 29.44, thus changing their proficiency levels from "Weak" to "Good/Excellent," which is far better than the control group.

Participation Rate: The percentage of students showing interest in the course was able to rise to 77.78% due to less pressure on the part of having to draw things manually and receiving diagnostic feedback.

Efficiency in Teaching: The use of AI feedback enables a teacher to instruct up to 80 students simultaneously.

6.2. Recommendations for Implementation

Based on the research results, we offer the following specific recommendations for English departments at HUFLIT and equivalent training institutions:

Develop an official AI Usage Guide: Universities should establish flexible policies that allow and guide students to use AI for scaffolding-related tasks such as preliminary structural analysis and diagram sketching.

Integration of Prompt Literacy into the Syllabus: The learners should be able to study linguistics as well as come up with theoretical AI prompts that do not have any ambiguity and avoid misinterpretations.

Hybrid Feedback Approach: The method where the AI program will provide the draft feedback while the teachers develop the final feedback for cultural and academic correctness is highly significant. • Technology Spending: The technology spending for the

hybrid feedback strategy should entail spending on high-speed internet and technological learning methods, including teacher training on the "AI-TPACK" principle.

6.3. Lessons Learnt and Future Perspective

The most important learning here is that AI is a “double-edged sword,” in the sense that whereas AI helps students to be “powerful innovators,” it could be harmful to independent thought if not used wisely in an educational setting. The lecturers are no longer knowledge providers; instead, they need to metamorphose into cognitive experience designers and critical discourse facilitators.

In terms of outlook, it is essential to emphasize that the integration of foreign language competence and digital literacy remains a vital competitive edge in HUFLIT education. In future research, the focus may be shifted toward investigating how students retain their knowledge through AI, as well as how novel multimodal approaches influence the analysis of increasingly complex clauses. In conclusion, the study of syntax in the age of the computer is not about the metaphorical planting of trees; rather, it is about discovering a method to create synergy with technology to reveal the mysteries of the human mind.

Bionote

Nguyen My Phuong is a lecturer of English at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT), Vietnam. She specializes in TESOL, with a research focus on artificial intelligence in language teaching, second language acquisition, and IELTS pedagogy. She has extensive experience teaching English to university students, particularly in phonetics, morphology, and syntax courses. Her recent work explores the integration of AI tools to enhance learners’ communicative competence and academic performance. She is currently involved in research on AI-assisted language learning and assessment in EFL contexts.

Appendix A

Syntactic Competence Rubric

This rubric is designed to assess the three domains consistently across both tests.

Criteria	1 - Beginning	2 - Developing	3 - Proficient	4 - Mastery
Conceptual Understanding	Misidentifies core terms (e.g., confusing 'Head' with 'Specifier').	Defines terms correctly but fails to explain the logic behind X-bar rules.	Accurately explains theory; understands the 'Single-bar' necessity.	Demonstrates deep insight into theory; explains recursion and projection.
Applied Knowledge	Cannot distinguish between complements and adjuncts.	Identifies functions correctly in simple NPs but fails in VPs or PPs.	Consistently distinguishes Specifier, Complement, and Adjunct functions.	Perfectly labels functions even in complex, nested, or ambiguous phrases.
Structure (X-Bar Trees)	Trees are flat; lacks intermediate projections or incorrect branching.	Basic X-bar structure is present but contains labeling errors or crossed lines.	Accurate tree structure; correct binary branching and hierarchical height.	Flawless representation of complex structures, including correct trace/movement.

Appendix B

Pre-Test: Foundational Syntax

Section 1: True/False (Conceptual Understanding) (20 pts)

1. **Statement:** In X-bar theory, every phrase must contain a head of the same category (e.g., a Noun Head projects a Noun Phrase). **(True/False)**
2. **Statement:** An adjunct is structurally required by the head and is always a sister to the Head (X). **(True/False)**
3. **Statement:** The "Specifier" position in a Noun Phrase is typically occupied by a Determiner. **(True/False)**
4. **Statement:** Phrase markers (trees) are used to represent the linear order of words but not their hierarchical relationships. **(True/False)**

Section 2: Multiple Choice (Applied Knowledge) (20 pts)

1. In the phrase "the king of France," the string "of France" functions as:

   a) Adjunct b) Complement c) Specifier d) Head
2. Which of the following is an intermediate projection?

   a) XP b) X' c) X d) Head
3. The relationship between a Head and its Complement is one of:

   a) Sisterhood b) Adjunction c) Specifying d) Coordination
4. A recursive rule is one that:

a) Ends the sentence b) Only allows one modifier c) Can be applied repeatedly d) Is always exocentric

Section 3: Phrase Markers (Structure) (60 pts)

Draw full X-bar trees for:

1. [NP The student of syntax]
2. [VP quickly left the room]

Appendix C

Post-Test: Advanced Syntactic Analysis

Section 1: True/False (Conceptual Understanding) (20 pts)

1. **Statement:** One-substitution is a reliable test to distinguish between complements and adjuncts in a Noun Phrase. **(True/False)**
2. **Statement:** A single head can have multiple complements in a standard X-bar structure. **(True/False)**
3. **Statement:** Adjuncts are attached to the tree at the X' level, creating a recursive X' node. **(True/False)**
4. **Statement:** Movement (such as in questions) leaves a "trace" that preserves the original syntactic position. **(True/False)**

Section 2: Multiple Choice (Applied Knowledge) (20 pts)

1. In the sentence "He ate the cake with a fork," the PP "with a fork" is:

a) A complement of the Verb b) An adjunct of the VP c) A specifier of the NP d) The head of the VP

2. Structural ambiguity (e.g., "I saw the man with a telescope") is caused by:

a) Different word meanings b) Different possible tree attachments c) Spelling errors d) Lack of a head

3. Which node is a sister to X' and daughter of XP?

a) Complement b) Adjunct c) Specifier d) Head

4. According to Burton-Roberts, the "S" node is replaced in X-bar theory by:

a) NP b) VP c) IP (or TP) d) PP

Section 3: Phrase Markers (Structure) (60 pts)

Draw full X-bar trees for:

1. [NP A very tall teacher of English with a book]
2. [IP The students might believe that the exam is easy]

Appendix D

QUESTIONNAIRE

Students' Perceptions of AI-Supported Instruction in Learning English Syntax

Section 1: Participant Information

1. Gender

- Male
- Female
- Prefer not to say

2. How long have you been learning English?

- Less than 5 years
- 5–10 years
- More than 10 years

3. Have you used AI tools before this course?

- Yes
- No

Section 2: Behavioral Engagement

Instruction:

Please indicate your level of agreement with the following statements. (Scale: 1 = Strongly Disagree 2= Quite Disagree 3= Disagree 4= Agree → 5 = Strongly Agree)

1. I actively participated in AI-supported syntax learning activities.
2. I completed assigned tasks using AI tools regularly.
3. I spent more time practicing syntax with AI tools than in traditional classes.
4. I followed instructions carefully when using AI tools.
5. I was willing to explore additional AI-based exercises beyond requirements.

Section 3: Cognitive Engagement

6. AI tools helped me understand sentence structure more clearly.
7. I was able to analyze complex sentences more effectively using AI.
8. AI tools helped me identify grammatical constituents (e.g., NP, VP, PP).
9. I could construct syntactic tree diagrams more accurately after using AI tools.
10. AI tools encouraged me to think more deeply about sentence structure.

Section 4: Emotional Engagement

11. I found learning syntax with AI tools enjoyable.
12. AI-supported lessons made syntax learning more interesting.
13. I felt more confident when analyzing sentence structures using AI.

14. AI tools reduced my anxiety when learning syntax.
15. I felt motivated to learn syntax when using AI tools.

Section 5: Perceived Usefulness (TAM)

16. AI tools are useful for learning English syntax.
17. AI tools improve my performance in syntax tasks.
18. AI tools make learning syntax more efficient.
19. AI tools help me achieve better learning outcomes.

Section 6: Perceived Ease of Use (TAM)

20. AI tools are easy to use.
21. I can use AI tools without much difficulty.
22. It is easy to learn how to use AI tools for syntax learning.
23. I feel confident using AI tools independently.

Section 7: Behavioral Intention

24. I would like to continue using AI tools for learning English syntax.
25. I would recommend AI tools to other students.

Section 8: Open-Ended Questions *(Short Answer)*

26. What do you like most about using AI tools in learning syntax?
27. What difficulties did you experience when using AI tools?
28. Do you have any suggestions to improve AI-supported syntax learning?

Appendix E

This set of 20 prompts is specifically designed for X-bar theory. The prompts are divided into levels, from introductory concepts to complex analysis, allowing sophomores to interact with AI as if it were a one-on-one teaching assistant.

Group 1: Understanding the Basic Structure of X-bar (X-bar Schema)

1. Explain the X-bar diagram: "Explain the basic X-bar diagram structure consisting of 3 levels: Specifier, Head, and Complement. Why is this structure superior to the traditional direct branching structure (Phrase Structure Rules)?"

2. Identify the Head (Central Word): "In the phrase [fill in the phrase, for example: 'very proud of his son'], identify the Head (X), the Complement, and the Specifier according to X-bar theory. Explain why."

3. Distinguishing Adjunct and Complement: "How do you differentiate between Adjunct and Complement in an X-bar diagram? Give an example illustrating the difference in their positions on the syntax tree."

4. Recursion Rule: "Explain the recursion of Adjunct in X-bar theory. Why can we have multiple X-prime levels (X') for Adjunct but only one for Complement?"

Group 2: Tree Drawing Practice (Coding for Tree Drawing Tools)

5. Creating Labelled Bracketing Code (Basic): "Analyze the noun phrase (NP) 'the long road to success' according to X-bar theory and provide Labelled Bracketing code for me to paste into the Syn tree plotter. Note that the N-prime levels must be clearly shown."

6. Sentence Structure (IP/TP): "Analyze the sentence 'The student will pass the exam' using either an Inflectional Phrase (IP) or a Tense Phrase (TP). Identify the Head of the IP and explain why."

7. Verb Phrase Structure (VP): "Draw the X-bar structure for the VP phrase: 'read the book in the library'. Note that 'in the library' is an Adjunct."

8. Adjective and Prepositional Phrases (AP & PP): "Analyze the X-bar structure for the phrase 'quite fond of cats'. Show the similarity between this AP structure and the NP structure."

Group 3: Analysis of Advanced Concepts

9. DP Hypothesis: "Why, in modern X-bar theory, is 'the book' analyzed as a Determiner Phrase (DP) instead of a Noun Phrase (NP)? Draw the DP structure for this phrase."

10. C-command and structural relationships: "Explain the concept of a C-command within the context of an X-bar tree. In the sentence 'John's mother loves herself,' use a C-command to explain why 'herself' refers to 'mother' and not 'John.'"

11. Complementary Phrase (CP) analysis: "When a sentence acts as a complement (e.g., 'I think that he is honest,'), how is the CP structure formed? Draw an X-bar tree for this sentence."

12. Question structure (Wh-movement): "Explain how X-bar theory handles Wh-questions (e.g., 'What did you eat?'). Indicate the position of the CP specifier and the trace of the question word."

Group 4: Critical Thinking

13. Self-Correction: "I intend to plot the phrase 'students of syntax with long hair' with 'with long hair' as a Complement of N. Is this correct? Please use syntax tests (such as Substitution 'one') to verify this for me."

14. Model Comparison: "Compare how a negative sentence is analyzed between the simple IP model and the Split-INFL model (separating AgrP, TenseP, NegP). Which one adheres more strictly to the X-bar rule?"

15. Adverb Handling: "Where should the adverb in the sentence 'He often eats pizza' be placed in the VP's X-bar diagram? Explain the Specifier vs. Adjunct position for adverbs."
16. Binary Branching: "Why does X-bar theory require binary branching (only splitting into 2)? How does this help in solving ambiguous sentences?"

Group 5: Challenges and Self-Practice Exercises

17. Create an exercise: "Give me 5 English phrases with complex structures (including Adjunct and Complement) and ask me to identify their X-bar structure. Then grade my answer."

18. Role-play as a Tutor: "Imagine you are a syntax teacher. I will describe how I draw an X-bar tree, and you find the logical error in my hierarchical structure."

19. Analyzing a Real Sentence: "Take a headline from today's newspaper and analyze it using a top-level X-bar diagram (including DP, TP, CP)."

20. Summary of the rule: "Create a summary table of the Golden Rules for drawing X-bars so that I never violate the rules regarding the placement of Heads, Specifiers, and Complements."

Note to students: AI can confuse different schools of linguistics. When using these prompts, students should refer to the main textbook in class (e.g., the textbooks of Noel Burton -Roberts, Andrew Carnie, or Liliane Haegeman) to ensure consistency.

#55 A Literature Review of Appraisal Theory in Language Education: Research Developments and Implications for ESL Teaching

Phan Tuan Ly[1], Hoang Ngoc Thanh Truc[2,3] & Pham Thi Thuy Dung[2,3]

Abstract

This study investigates the development of research on applying Appraisal Theory (Martin & White, 2005) in language education using a bibliometric approach. Grounded in Systemic Functional Linguistics, Appraisal Theory provides an analytical framework for examining how language users express emotions, attitudes, and evaluations in authentic contexts, and has increasingly attracted attention for its pedagogical potential. Using articles indexed in Scopus from 2006 to 2026, 48 publications were selected according to predefined inclusion criteria and analyzed with VOSviewer. The results show that Australia leads the field by a substantial margin. After a decline prior to 2020, the number of publications recovered and continued to rise, reaching a second peak in 2024. Two journals- *Journal of English for Academic Purposes* and *Linguistics and Education*- were identified as the most prominent outlets in this research area. Highly influential scholars include Yadan Li, Ana Llinares, and Ryan T. Miller, while Hood (2006) emerged as the most cited work. The bibliometric analysis further revealed six major clusters concerning the application of Appraisal Theory to foreign language teaching. Overall, the findings indicate that Appraisal Theory is becoming increasingly central to the modernization of English language teaching in Vietnam.

***Keywords*:** appraisal theory, bibliometrics, SFL, ESL teaching, language education

1. Introduction

Appraisal Theory is an essential branch of Systemic Functional Linguistics (SFL) that addresses how language expresses the attitudes, evaluations, and viewpoints of speakers and writers. Appraisal Theory has proved a useful tool in discourse studies, especially in language education, where it is especially important for understanding how learners construe attitudes and feelings and also as a way of exploring interpersonal meaning.

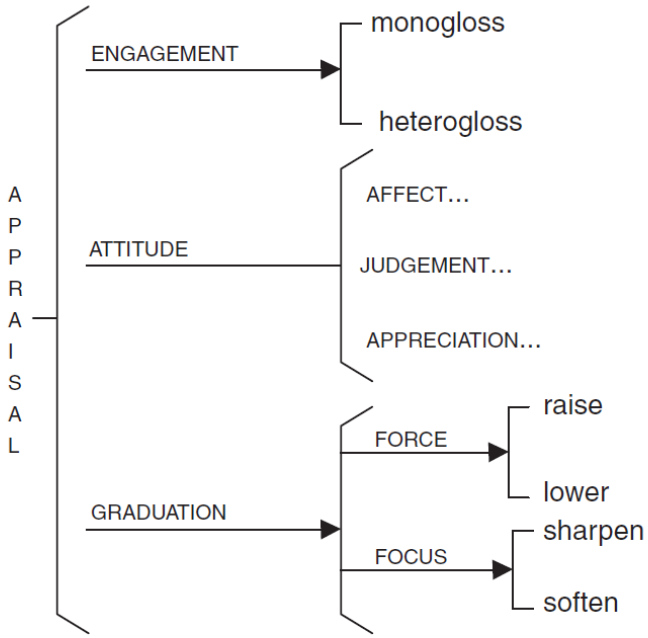
The Appraisal Theory has been widely used worldwide in foreign language teaching research, academic text analysis, and evaluation of learners' writing competence. In Vietnam, however, although the framework has been introduced and used in some studies, its application remains limited, particularly in pedagogical contexts involving English as a Second Language (ESL). Therefore, the mapping of the current research status of Appraisal Theory in language education not only helps Vietnamese scholars to see the research status in the world but also provides orientations for the application of this theory to teaching and researching.

This research tries to examine the development of research on Appraisal Theory Application in language education throughout the years. Two central research questions are posed: (1) What is the current scholarly output in this field in terms of volume of publications, journals, and authors contributing? (2) What are the major research thematic areas, and what are the changes at different stages of development? These questions provide a holistic view of research trends and identify the gaps that need exploration.

[1] *PhD; Faculty of Legal Foreign Languages; Ho Chi Minh City University of Law; Ho Chi Minh City, Vietnam;*
[2] *MA; Faculty of Legal Foreign Languages; Ho Chi Minh City University of Law; Ho Chi Minh City, Vietnam;*
[3] *PhD Candidate; Faculty of Literature and Linguistics, University of Social Sciences and Humanities, Vietnam National University Ho Chi Minh City; Email: pttdung@hcmulaw.edu.vn*

For this purpose, this paper takes into account past research, publication trends, and major topics. The article is structured as follows: first, the literature review provides the conceptual foundations of Appraisal Theory, its main categories, and representative studies; second, the methodology, results, and discussion sections introduce the bibliometric analysis and thematic findings; finally, the conclusion summarizes key insights and offers pedagogical implications for ESL teaching in Vietnam.

In summary, this study aims to offer a comprehensive and coherent account of the evolution of Appraisal Theory in language education, which will help researchers and ESL educators in improving their understanding and in the effective application of this framework in both teaching and research contexts.



2. Literature Review

Martin and White (2005), building on the foundations of Systemic Functional Grammar (SFG), developed Appraisal Theory to extend the scope of interpersonality analysis in discourse. Whereas SFG primarily describes the linguistic resources through which meanings are construed, Appraisal Theory advances this perspective by establishing a systematic relationship between linguistic form and the social functions that language performs in particular communicative contexts. Accordingly, the theory is concerned with how language users express attitudes, position themselves, and negotiate social relations through discourse.

According to Martin and White (2005), appraisal constitutes an interpersonally oriented semantic system that enables discourse participants to communicate feelings, propositions, viewpoints, and the degree of commitment associated with their utterances. As such, the framework offers a methodological basis for identifying and explaining how stances are realized across diverse discourse types. As illustrated in Figure 1, the Appraisal System comprises three interrelated subsystems: Attitude, Engagement, and Graduation. In combination, these components respectively account for (i) the expression of affective and evaluative meanings, (ii) the management of alternative sources of voice within discourse, and (iii) the calibration of intensity and explicitness of evaluative content.

Figure 1

An overview of appraisal resources

Source: Martin & White, 2005, p. 38

Within this framework, Attitude occupies the central function and is further differentiated into three categories: Affect, which encodes personal feelings; Judgment, which evaluates human behavior or personal attributes; and Appreciation, which assesses phenomena and objects. Graduation captures the degree of strength–weakness or explicitness–implicitness of evaluations through two mechanisms—Force and Focus—thereby reflecting the speaker/writer's strategies for modulating the perceived impact on the addressee (Phan, 2022). Engagement concerns the sourcing of viewpoints in discourse and distinguishes between monogloss (single-voiced) and heterogloss (multi-voiced) patterns. This distinction, in turn, reveals the extent to which texts are dialogically open to alternative perspectives.

The application of Appraisal Theory has emerged as a significant research trajectory in multiple disciplines, including literature, communication, law, and academic inquiry (Oteíza, 2017; Wei et al., 2015). By offering a structured approach to organizing evaluative linguistic resources, the theory enables researchers not only to identify affective and evaluative elements, but also to examine how discourse participants construct stances, organize arguments, and cultivate social interaction within particular cultural and sociopolitical settings (Callon et al., 1983; Caputo et al., 2019).

3. Methodology

3.1. Database and Searching Process

This study conducts a bibliometric analysis using publication data retrieved from Scopus. The search was restricted to records containing the keywords "appraisal" and "Systemic Functional Linguistics." The initial Scopus query yielded 303 articles matching both keywords. In this paper, we also employ keywords related to the field of translation, specifically "Translation" and "Legal Translation." The inclusion of these keywords is justified by the close relationship between translation and language education, particularly in fostering learners' linguistic competence and discipline-specific professional competence. After applying the exclusion criteria specified in Table 1 and limiting the scope to the education

domain, the final corpus comprised 48 English-language articles. These were subsequently used to examine research trends related to this topic.

The Scopus query employed to retrieve the articles is as follows:

TITLE-ABS-KEY (“appraisal” AND “systemic functional”) AND PUBYEAR > 2005 AND PUBYEAR < 2027 AND (LIMIT-TO (DOCTYPE, “ar”) OR LIMIT-TO (DOCTYPE, “cp”)) AND (LIMIT-TO (LANGUAGE, “English”)) AND (LIMIT-TO (EXACTKEYWORD, “Academic Writing”) OR LIMIT-TO (EXACTKEYWORD, “Argumentative Writing”) OR LIMIT-TO (EXACTKEYWORD, “Translation”) OR LIMIT-TO (EXACTKEYWORD, “Teacher Education”) OR LIMIT-TO (EXACTKEYWORD, “Students”) OR LIMIT-TO (EXACTKEYWORD, “Graduation Resources”) OR LIMIT-TO (EXACTKEYWORD, “History Textbooks”) OR LIMIT-TO (EXACTKEYWORD, “Academic Discourse”) OR LIMIT-TO (EXACTKEYWORD, “Legal Translation”) OR LIMIT-TO (EXACTKEYWORD, “L2 Writing”))

Table 1

Inclusion and exclusion criteria for selection of English papers

Criteria included	Criteria excluded
Language: English	Not connected to the keywords appraisal and Systemic functional Linguistics
Time: 2006-2026	Inadequate research
Article type: research articles and conference paper	Books, reviews, book chapters
Subject areas: social sciences; arts and humanities	Others

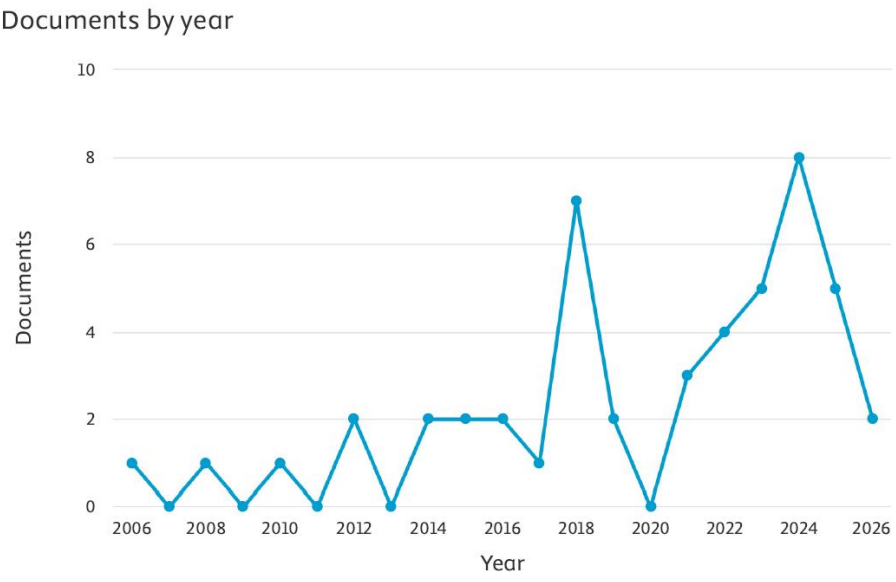
3.2. Bibliometric Methods

Bibliometric analysis is a methodological approach within scientometrics that applies statistical techniques to examine and evaluate scientific publications within defined subject areas (Broadus, 1987). It is primarily designed to achieve two objectives: (i) assessing research performance and (ii) mapping the structure of scientific knowledge (Aria & Cuccurullo, 2017). Performance analysis typically relies on activity-related indicators to measure the extent and contribution of research outputs, whereas scientific mapping uses relational indicators to characterize how knowledge is structured and evolves within a given field (Iwami et al., 2020).

In the present study, the software VOSviewer (van Eck & Waltman, 2007) is employed to analyze academic works containing the keywords “appraisal” and “Systemic functional Linguistics”. Following data collection, the dataset is processed to identify research trends through bibliometric techniques, such as bibliographic coupling, keyword co-occurrence, and co-occurrence based on abstracts. Bibliographic coupling enables the assessment of topical similarity across publications by examining shared cited references. Concurrently, analyses of keyword and abstract co-occurrences help reveal the conceptual organization of the research domain by identifying relationships among key terms (Callon et al., 1983). Overall, the findings show that keywords and abstracts form a densely connected vocabulary network, which plays a critical role in shaping the knowledge structure of the field (Caputo et al., 2019).

To visualize these patterns, the study uses network visualizations and term-density visualizations generated in VOSviewer. These visual outputs are used to clarify both the degree of interconnection among research themes and their relative frequency of occurrence.

4. Results



4.1. An overview of bibliometric data

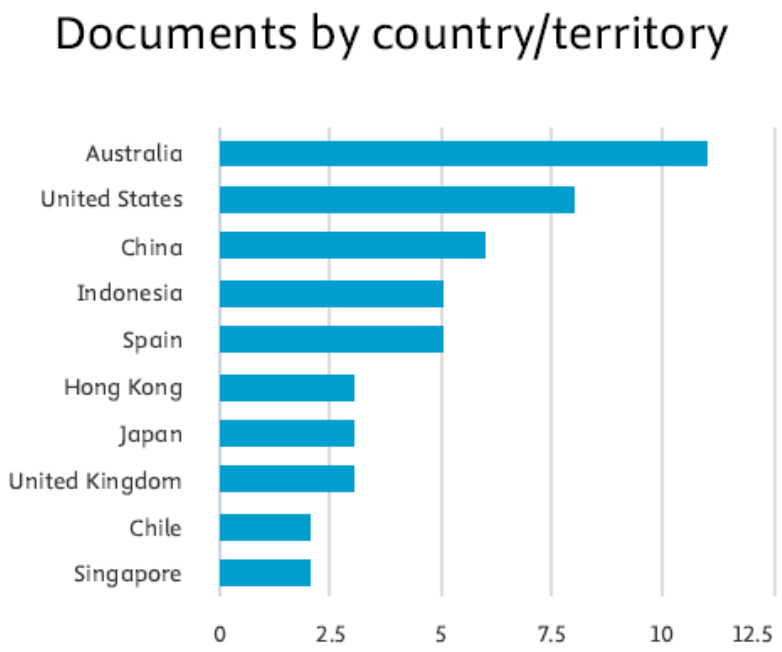
The chart below presents the number of documents published on Appraisal Theory per year (retrieved from Scopus). In the first decade (2006-2016), the number of publications was not high, with one to two articles per year, which shows the early stages of the research attention to Appraisal Theory. In the next 10 years, the number of publications, however, shows substantial fluctuation, which is a sign of the gradual expansion of research in this field. Accordingly, the figures reach their peaks in 2018 and 2024, which depicts that the academic interest in Appraisal Theory is thriving.

The year of 2020 with global phenomena such as the COVID-19 pandemic resulted in a decline in publications. Consequently, this destructively influenced research activities and the worldwide circulation of scholarly work. Afterwards, the number of publications resumed to grow, reaching a second peak in 2024. This recovery proved the resilience of the research community and the consolidation of Appraisal Theory- a more and more influential theoretical framework in language education.

Figure 2

Publication Trends of Appraisal Theory Research in 2006–2026

Source: Scopus, 2026



The number of publications on Appraisal Theory by country/territory is shown in Figure 3. The data shows that Australia has the most publications, by a wide margin over other countries. The United States and China rank the second with many research on Appraisal Theory. Thanks to the great diversity in their education, Indonesia and Spain witnessed the same trend with considerable quantity paper on the theory. Despite fewer publications, Hong Kong, Japan, the UK, Chile, and Singapore made important contributions to this field around the world. This graph shows that Appraisal Theory is widely used in many parts of the world, especially Asia, Europe, and America.

The distribution of locations shown here can be interpreted that Appraisal Theory has gained interest in various locations, including Asia, Europe, and America. This sets out that the

theory has earned its immense importance and flexibility in different linguistic and educational settings globally.

4.2. The Citation, co-citation, and bibliography coupling analysis

4.2.1. Productive Journals

Table 2 is the analysis of citation, co-citation, and bibliography coupling for important journals in Appraisal Theory research. The data marks the dominance of some journals compared to others. For instance, there are 5 documents, 147 citations, and a total link strength of 50 on the Journal of English for Academic Purposes. For the journal called Linguistics and Education, there are 2 documents worth 93 citations and a total link strength of 49. Therefore, this field is believed to have great influence. The evidence for great interest in Appraisal Theory in a bilingual context is the fact that International Journal of Bilingual Education and Bilingualism has 51 citations and 2 documents. Other sources like Indonesian Journal of Applied Linguistics, Written Communication, and An Introduction to Functional Grammar also help arouse researchers' interest in the field.

Overall, Table 2 shows that the research distribution is concentrated in major international journals and extends to regional sources. The combination of the number of documents, citations, and total link strength forms a comprehensive picture of the influence of each source, thereby highlighting the most important publication channels for scholars interested in Appraisal Theory in language education.

Table 2

Productive Journals in Appraisal Theory Research

	Citation			Co-Citation			Bibliographic Coupling			
	Source	Documents	Citations	Source	Citations	Total link strength	Source	Documents	Citations	Total link strength
1	Indonesian Journal of applied linguistics	2	2	An introduction to functional grammar	27	219	Indonesian Journal of applied linguistics	2	2	19
2	International Journal of Bilingual Education and bilingualism	2	51	Applied linguistics	28	400	International Journal of Bilingual Education and bilingualism	2	51	26
3	Journal of English for academic purposes	5	147	Assessing writing	25	209	Journal of English for academic purposes	5	147	50
4	Linguistics and education	2	93	English for specific purposes	34	494	Linguistics and education	2	93	49
5	Written communication	2	78	Evaluation in text: Authorial stance and the construction of Discourse	27	249	Written communication	2	78	34

4.2.2. Prolific Authors

Table 3 gives information about the most prolific authors in the field of Appraisal Theory on the basis of the indicators of documents, citations, and total link strength. These reflect the productivity of individual scholars and their academic impact and connectivity to the international research network. The data sets out a clear distinction between authors with many publications and low citations and authors with few publications and high citation counts. For example, Yadan Li with two documents (no recorded citations) and an overall link strength of 67, convinced others that her work is well embedded in the research network despite having a limited direct citation impact. Ana Llinares and Ryan T. Miller are two other authors who have also published two documents each, with 53 and 80 citations, respectively, which shows that they have made a major impact in this field. Gordon Mmyskow and Yilong Yang also each have three documents, and they have strong connectivity with total link strengths of 78 and 86, respectively, which shows their role in linking different strands of research.

Moreover, a number of long-standing influential scholars like M.A.K. Halliday, J.R. Martin, K. Hyland, S. Hood, and D. Rose appear to be distinguished with the number of citations from 24 to 58 and extremely high total link strengths (134–295). Those figures mark their roles in the evolution and utilization of Appraisal Theory. In summary, Table 3 demonstrates authors with considerable contributions to the research on Appraisal Theory,

from new scholars who have a strong connection to the network to established figures whose work on theory and pedagogy continues to influence the field.

Table 3

Prolific Authors in Appraisal Theory Research

	Citation			Co-Citation			Bibliographic Coupling			
	Author	Documents	Citations	Author	Citations	Total link strength	Author	Documents	Citations	Total link strength
1	Li, Yadan	2	0	Coffin C.	40	255	Li, Yadan	2	0	67
2	Llinares, Ana	2	53	Halliday M.A.K.	26	159	Llinares, Ana	2	53	39
3	Miller, Ryan T.	2	80	Hood S.	34	182	Miller, Ryan T.	2	80	47

6	Yang, Yilong	3	4	Rose D.	24	134	Yang, Yilong	3	4	86

4.2.3. Highly Cited Article

The list of highly cited articles in the field of Appraisal Theory is displayed in the table below. They are influential works in studies on Systemic Functional Linguistics and language education. Apparently, Hood (2006) has the highest number of citations (108) with the total link strength of 16. The figures imply his influence upon subsequent research. Lancaster (2014) and Miller (2014) also show a strong impact with 77 and 74 citations, respectively, which shows the rising interest of scholars in the application of Appraisal Theory to the analysis of academic texts and discourse studies. Lately, the works by Whittaker (2020) and Szenes (2021) portray the development of Appraisal Theory in modern settings. Those suggest the role of this theory in changing educational and linguistic issues. The scholarly works like An Introduction to Functional Grammar (Halliday, 1994), Working with Discourse: Meaning Beyond the Clause (Martin and Rose, 2007) and Evaluation in Text: Authorial Stance and the Construction of Discourse (Hunston and Thompson, 2000) reaffirm their foundational role in the theoretical setting up of Appraisal.

In short, the table indicates a harmony between classical works and more recent applications. The most frequently cited articles suggested the influence of the theory. At the same time, the new studies reflected the diversification of Appraisal Theory into new domains. The pairing highlights the continuance and vibrancy of research within the domain of language education and additionally consolidates the position of Appraisal Theory as a powerful and thriving analytical instrument.

Table 4

Highly Cited Articles in Appraisal Theory Research

4.3. The Co-occurence analysis

The results of the co-occurrence analysis will identify prominent research trends in recent years and, simultaneously, indicate the degree of keyword prominence (density)—that

is, the extent to which particular terms attract scholarly attention and reflect sustained interest within the field.

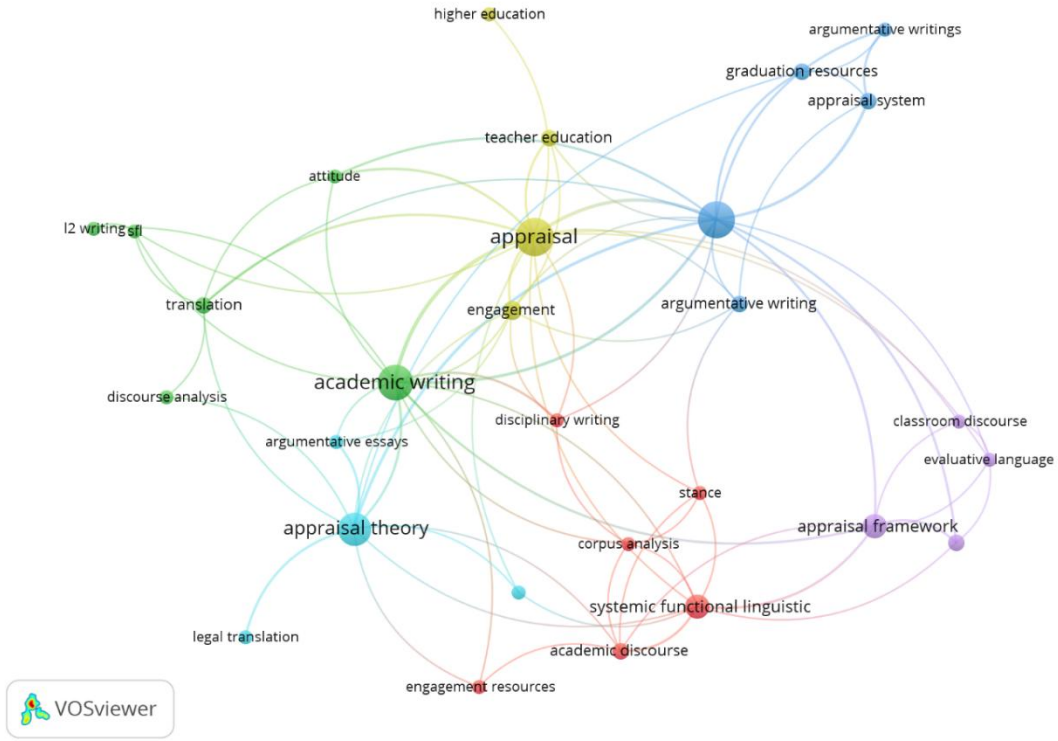
4.3.1. Dominant Trends

Figure 4 identifies six prominent clusters regarding the application of Appraisal theory to foreign language teaching. Overall, the clustering structure suggests a diversity of implementation scopes and, at the same time, delineates key research directions through central keywords and their discourse-linked networks.

Cluster 1 (yellow) is located in the upper portion of Figure 4, with the central keyword "appraisal" linked to "teacher education," "higher education," and "engagement." This cluster indicates a research trajectory that employs Appraisal theory as an analytical framework to support teacher education, extending to instructional contexts at both undergraduate and postgraduate levels. Notable scholars include Adlington et al. (2024), Godoy-Echiburú and Flores-Calvo (2025), and Nurhadi et al. (2024).

Cluster 2 (green), positioned on the left side of Figure 4, has "academic writing" as the central keyword and connects to "translation," "discourse analysis," "L2 writing," "SFL," and "attitude." The cluster reflects research on teaching academic writing, where discourse analysis is treated as a foundational tool for explaining and guiding text production. Importantly, the outcomes of discourse analysis are also applied to translation studies and L2 writing instruction. Representative works include Munday (2012) and Yu and Wu (2018).

Cluster 3 (light blue) appears on the left, below Figure 4, using "appraisal theory" as the central keyword and showing prominent links to "argumentative essays" and "legal translation." This cluster represents a line of inquiry centered on analyzing texts for specific discourse purposes, particularly argumentative essays and legal translation. Representative authors include Cheung and Low (2017) and Geng et al. (2024).



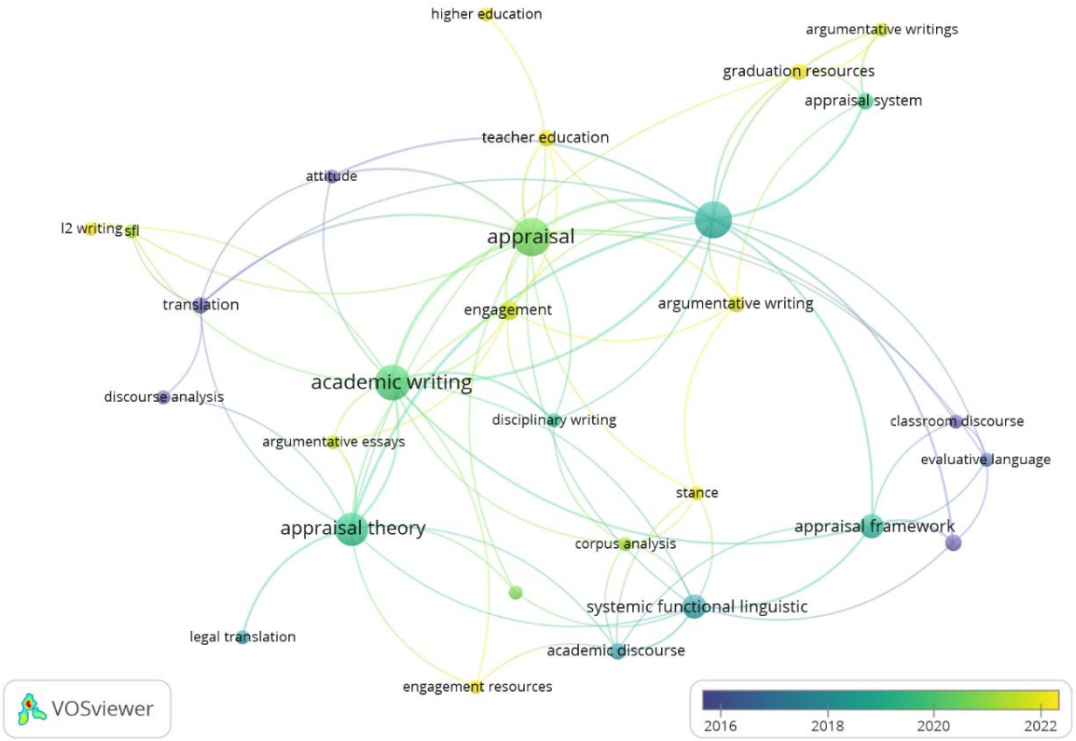
Cluster 4 (red) is located at the bottom of Figure 4, with "Systemic Functional Linguistics" as the central keyword. It is linked to "disciplinary writing," "stance," "corpus analysis," "academic discourse," and "engagement resources." This trend emphasizes investigating interpersonal relations in academic texts and connecting such insights to discipline-specific writing practices. Representative studies include Reznicek-Parrado et al. (2018) and Cederholm (2025).

Cluster 5 (purple) is situated on the right side of Figure 4. With "appraisal framework" as the central keyword, it connects to "classroom discourse and evaluative language." This cluster suggests growing interest in analyzing classroom discourse and evaluative language in educational settings. Representative authors include Cavanna et al. (2015) and Myskow (2018).

Cluster 6 (sky blue) is also located on the right side of Figure 4, taking "argumentative writing" as the central keyword and linking to "graduation resource" and "appraisal system." The principal research direction in this cluster concerns the analysis of graduation in texts intended for argumentative writing. Representative scholars include Yang (2016) and Vo and Le (2025).

Figure 4

Dominant Trends of Appraisal Theory



4.3.2. New research trends in the last five years

Figure 5 synthesizes prominent research trends observed over the past five years. The keywords highlighted in bright yellow—L2 writing, higher education, argumentative writings, graduation resources, engagement, and stance—are highly concentrated, indicating that recent studies have largely focused on leveraging appraisal resources, particularly engagement and graduation, to address core issues closely related to writing instruction at the university level. These findings also demonstrate the applicability of appraisal theory in higher education contexts, as evidenced by representative studies such as Cederholm (2025), Hutasuhut et al. (2023), and Ilić (2022).

Figure 5

New research trends in Appraisal Theory over the last five years

4.3.3. Trend Capturing Scholarly Attention

Structurally, within the appraisal theory framework, the keywords highlighted in dark yellow operate as central nodes and maintain direct linkages with the associated research content. Specifically, most studies in this cluster foreground appraisal and appraisal theory. Moreover, among the key terms, academic writing and argumentative writing exhibit comparatively high density, suggesting that these represent the two most distinctly emphasized research directions. This pattern implies that scholars prioritize using appraisal theory to explain and analyze linguistic phenomena related to the construction of academic texts, while also using such insights to inform the design of teaching and learning activities aligned with writing objectives.

Figure 6

Trends Capturing Scholarly Attention in Appraisal Theory

Overall, Figure 6 suggests that the effectiveness of appraisal theory for teaching writing skills has been widely recognized in recent scholarship, as reflected in studies such as Ndoricimpa and Barad (2024) and Li (2024).

4.4. Discussion on the Feasibility of Appraisal Theory in ESL Teaching in Vietnam

In spite of a strong position in linguistics, the application of Appraisal Theory to English as a Language (ELT) teaching in Vietnam remains a potential gap that has not been adequately explored. However, recent studies have been proving the feasibility and high practical value of this theory in complementing the academic competence of Vietnamese learners.

Indeed, Appraisal Theory has indicated its power in contouring 'writers' authorial voice' which is believed to be a key element of academic discourse. Vo an Le (2025) inspected the use of Graduation resources in TESOL master's theses by Vietnamese EFL learners. This research confirms the essential role of instructions in Appraisal Theory for helping students manage professional and persuasive academic voice. Similarly, Chung and Crosthwaite (2024), found significant differences in the expression of attitudes between native English speakers and Vietnamese learners who use English as second language. The fact that the latter often express themselves too directly but lack diversity in their choice of assessment language. This demonstrates that Appraisal Theory is necessary for teachers to guide learners in conveying attitudes subtly and for examiners to more accurately assess academic stances.

Apart from written texts, the elasticity of Appraisal Theory is also displayed in studies of spoken discourse. Ngo and Unsworth (2015) suggested powerful clarifications to the

Attitude system based on group discussion data from graduate students in both English and Vietnamese. These improvements enrich the theoretical framework and at the same time provide valuable learning resources to enhance the effectiveness of expressing students' positions in multilingual contexts.

In addition to the desired results brought about for language learning, especially for teaching English as second language, this theory can be used as a dynamic accompanying framework to evaluate learners' perceptions of technology support in education. Ngan and Le (2025) delivered a study adopting Appraisal Theory. Their paper explores the awareness of 450 students and 12 teachers about the use of Google Translate. The results of this study bring up penetrating perspectives for policymakers on the role of technology. In addition, they confirm that Appraisal Theory is a functional tool capable of comprehensively improving the teaching and learning of foreign languages by understanding attitudes and promoting ethical technology use.

Although the application of Appraisal Theory appeared not to arouse much attention from researchers in Vietnam, the aforementioned studies have soundly established its implication in both general linguistics and teaching English as a Second Language (ESL). In short, the practicality of Appraisal Theory extends a broad range of academic needs—from decoding the complexities of argumentative writing and spoken discourse to evaluating user perceptions of emerging educational technologies. This implication proves that the framework is a descriptive linguistic tool and it also offers a practical, far-reaching methodology for classroom variation. As educators and researchers have had a shift to more communicative and evaluative-based instruction, Appraisal Theory has been becoming a central part in the modernization of English language teaching in Vietnam. Its adoption assures the prospect that learners are able to employ the “evaluative literacy” necessary to navigate the demands of global academic and professional discourse with confidence and precision.

5. Conclusion

In this paper, we mapped the research landscape of applying Appraisal theory in language education by examining publication development, research trends, and the feasibility of this theory within the context of Vietnam. Overall, the field has shown a clear recovery and growth trajectory: after 2020, publication numbers rebounded and continued to rise, reaching a second peak in 2024. In terms of international contributions, Australia leads the field by a wide margin over other countries. At the journal level, *Journal of English for Academic Purposes* and *Linguistics and Education* emerged as the two most prominent venues in this research area. The analysis of authorship impact further indicates that Yadan Li, Ana Llinares, and Ryan T. Miller are key contributors shaping scholarly influence in this domain, while Hood’s (2006) work remains the most cited and has exerted substantial impact on subsequent studies.

Beyond identifying major outlets, authors, and influential prior research, the present study also explored six prominent clusters related to the application of Appraisal theory to foreign language teaching. Importantly, the findings suggest that Appraisal Theory is increasingly becoming a central component in the modernization of English language teaching in Vietnam, offering meaningful theoretical and practical value for advancing how language evaluation, interpersonal meaning, and textual stance can be analyzed and taught in educational settings.

Although bibliometric analysis enables the identification and generalization of research trends regarding the application of Appraisal Theory in foreign language education using

Scopus data, this approach presents several limitations. First, the findings are highly contingent on the selection and frequency of keywords. Consequently, less common keywords—or terms not captured within the principal keyword cluster—may be underrepresented, which can distort estimates of the research community's attention to particular topics (Zahra et al., 2021). In addition, newly published studies, especially exploratory work or research that has not yet attracted substantial citation uptake, may not be fully indexed in the database, resulting in gaps within the analytical dataset (Thelwall, 2018). These constraints are partly attributable to the indexing characteristics of bibliographic databases, particularly open-access data infrastructures.

Second, restricting the analysis to a single database (e.g., Scopus) may limit the comprehensiveness of the study, as relevant publications are not always indexed within the same system. To mitigate these issues, future research should integrate multiple bibliographic sources and adopt complementary analytical methods. For example, time-series trend analysis and author-based citation network construction could be used alongside bibliometric indicators to provide a more nuanced and robust account of how the field has evolved over time. Collectively, these strategies would improve both the completeness and accuracy of the evidence regarding the development of this research area.

Ly Tuan Phan earned a PhD in Contrastive Linguistics from the University of Social Sciences and Humanities, Ho Chi Minh City - Vietnam National University. He is currently a lecturer at Ho Chi Minh City University of Law. His research interests include legal discourse and Systemic Functional Linguistics.

Truc Ngoc Thanh Hoang holds an MA in Linguistics and is currently a lecturer at Ho Chi Minh City University of Law. With a focus on the intersection of linguistics and law, her scholarly interests include legal discourse analysis and the application of linguistic theories to the study and teaching.

Dung Thi Thuy Pham holds an MA in TESOL and is currently a PhD candidate in Contrastive Linguistics. With a background in English language pedagogy, her research has evolved to specialize in the intersection of language and law. Her current scholarly work focuses on legal English teaching and the linguistic nuances of legal discourse. Looking forward, her research interests involve contrastive linguistics within legal frameworks, specifically examining the structural and functional disparities between legal languages.

#56 Exploring Undergraduate Students' Use of AI for Academic Presentations in Higher Education

Nguyễn Thị Hồng Liên[1], Nguyễn Thị Thanh Vân[2]

Abstract

This study examines undergraduate students' self-reported use of generative artificial intelligence (GenAI) for academic presentation design and their evaluations of its usefulness and ease of use. Survey data were collected from 197 undergraduate students at a Vietnamese university. The study used descriptive statistics, multiple-response analysis, reliability testing, factor-based measurement validation, and K-means clustering to analyze GenAI usage patterns, task delegation, and student perceptions. The findings show that GenAI had become a routine support tool, with 86.8% of students reporting weekly or daily use. However, frequent use did not necessarily indicate full dependence, as most students reported moderate task delegation. Students used GenAI most often for content preparation and less often for live presentation tasks, suggesting an asymmetric pattern of delegation across the presentation workflow. Three user profiles emerged: Power Integrators, Selective Minimalists, and Skeptical Delegators. These profiles show that students differed not only in usage frequency, but also in tool diversity, task delegation, perceived autonomy, and attitudes toward GenAI. Students evaluated GenAI positively in terms of perceived usefulness and ease of use, but valued it more for immediate productivity than for long-term presentation skill development. The study highlights the need for pedagogically guided GenAI integration, particularly in relation to task delegation, output evaluation, disclosure, and reflective revision.

***Keywords*:** GenAI, academic presentation, higher education, student perception

1. Introduction

Generative artificial intelligence (GenAI) has rapidly transformed the landscape of higher education, evolving from a technological novelty into an embedded educational resource (Lim et al., 2023). Following the public release of large language models like ChatGPT, students have gained unprecedented access to tools that can generate human-like text, synthesize complex information, and assist in multifaceted academic tasks (Dwivedi et al., 2023). This rapid proliferation has shifted institutional discourses from initial attempts at prohibition to a growing recognition of the need for AI literacy, ethical integration, and human-centered pedagogical strategies (UNESCO, 2023). Consequently, GenAI is no longer viewed merely as an external disruption but as a permanent fixture in the academic ecosystem that demands rigorous empirical investigation.

Understanding how undergraduate students utilize GenAI for academic work is particularly crucial. As the primary early adopters of these technologies, university students—especially those belonging to Generation Z—exhibit a strong willingness to employ GenAI to enhance their productivity, digital competence, and learning efficiency (Chan & Lee, 2023). Student perceptions and interactions with their learning environments directly influence their educational approaches and eventual outcomes (Chan & Hu, 2023). While AI systems offer significant advantages, such as providing personalized feedback, facilitating brainstorming, and overcoming language barriers, they also pose profound challenges. Educators frequently

express concerns regarding over-reliance, diminished critical thinking, and the potential illusion of comprehension when students outsource cognitive labor to algorithms (Kim et al., 2024; Sullivan et al., 2023). Therefore, empirical investigations into students' reported usage patterns and AI-supported academic practices are essential.

Within the spectrum of academic assignments, academic presentations represent a uniquely demanding, multimodal activity. Developing an effective presentation requires students to synthesize rigorous research, conceptual organization, visual design, and oral delivery (Chu et al., 2025). The emergence of GenAI has introduced new mechanisms for cognitive offloading in this space, enabling students to utilize AI-assisted tools for organizing information, outlining narratives, and formatting visual slides (Georgiev & Tinsley, 2024). However, despite the inherent complexity of presentation design and the increasing availability of both text-based and multimodal GenAI tools, this specific domain remains an underexplored area of student AI use.

Current research has not fully captured how students report using GenAI across different academic tasks. Most studies only show general statistics about GenAI use for academic writing, rather than examining how students use it for different parts of complex tasks like presentations or how usage differs among different groups of students. Furthermore, while the Technology Acceptance Model (TAM) has been widely applied to assess educational technologies through its core constructs of Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) (Davis, 1989; Venkatesh et al., 2003), its application to GenAI requires further scrutiny. For conversational AI tools whose primary interface is natural language, the traditional boundary between a tool's utility and its operational effortlessness may become increasingly blurred (Strzelecki, 2023). It remains unclear whether PU and PEOU retain their conceptual distinctness in design-oriented contexts, highlighting a significant gap in understanding how students genuinely evaluate these tools.

To address these theoretical and empirical gaps, the present study aims to explore undergraduate students' reported usage patterns of GenAI for academic presentation design. By identifying detailed usage patterns, examining the extent of task delegation across different presentation stages, and analyzing students' evaluations of these tools, this research provides essential insights into the intersection of AI adoption and academic design tasks. Specifically, this study is guided by the following two research questions:

- **RQ1.** How do undergraduate students use GenAI for academic presentation design, particularly in terms of usage patterns and task delegation?
- **RQ2.** How do students evaluate GenAI tools for academic presentation design in terms of perceived usefulness and perceived ease of use?

2. Literature Review

2.1. Integration and Usage Patterns of Generative AI in Higher Education

The integration of Generative Artificial Intelligence (GenAI) is catalyzing a paradigm shift in educational practices, moving institutional focus from strict prohibition to the development of AI literacy and critical interaction skills (UNESCO, 2023). GenAI has rapidly transitioned from a technological novelty to an embedded educational tool, fundamentally changing the landscape of higher education (Lim et al., 2023). Students have quickly adopted tools such as ChatGPT for a wide array of academic tasks, recognizing their capacity to provide personalized, real-time support (Chan & Hu, 2023). A recurring theme in the literature is the conceptualization of GenAI as a versatile, multi-tasking assistant. Students frequently use these

tools to brainstorm ideas, retrieve information, and refine their writing, effectively treating the AI as a virtual tutor or a digital peer during their academic workflows (Kim et al., 2024). Furthermore, research highlights a distinct generational enthusiasm, with Generation Z students demonstrating a strong willingness to integrate GenAI to enhance their productivity, digital competence, and overall academic efficiency (Chan & Lee, 2023). Students are increasingly positioned as active users who interact with GenAI to test ideas, explore perspectives, and support academic meaning making (Kim et al., 2024). However, research also shows that students do not all use GenAI in the same way. How much and how well they use it often depends on their previous experience with technology, their motivation to learn, and their field of study (Chu et al., 2025; Li et al., 2026). While some learners actively exploit the multimodal capabilities of GenAI to explore creative problem-solving and conceptual abstraction, others limit their engagement to superficial tasks like grammar correction and basic translation (Chu et al., 2025; Ngo, 2023). Because of these differences, researchers should not only look at overall rates of AI use. They also need to examine how different groups of students use GenAI in specific ways for their academic work.

2.2. Task Delegation in Multimodal Academic Presentations

Academic presentations represent a uniquely demanding educational activity that requires students to synthesize rigorous research, coherent textual organization, and engaging visual design (Georgiev & Tinsley, 2024). The emergence of GenAI has introduced new possibilities for cognitive offloading and task delegation in this multimodal context. Creating presentations involves the cognitive challenge of harmonizing textual arguments with visual representations and oral delivery. Research indicates that utilizing GenAI to manage these multimodal demands provides a supportive and inclusive environment, enabling students to express their ideas innovatively while maintaining their learning motivation (Chu et al., 2025). Studies indicate that students are increasingly leveraging GenAI, such as Microsoft PowerPoint Designer or ChatGPT, to organize information, format slides, and outline their academic presentations (Baker et al., 2024; Georgiev & Tinsley, 2024). These tools are praised for their ability to streamline the preparatory phases of presentation design, allowing students to save time and reduce the cognitive burden associated with visual structuring (Baker et al., 2024; Li et al., 2026).

Despite these affordances, research shows that students differ in how much control they are willing to give AI. While GenAI is frequently tasked with early-stage preparation—such as generating subtitles, synthesizing reading materials, and proposing structural outlines—students often exhibit caution when it comes to delegating the final design and performance elements (Georgiev & Tinsley, 2024; Kim et al., 2024). This reluctance stems from well-documented concerns about AI's limitations in contextual understanding, logical coherence, and the alignment of visual elements with textual meaning (Georgiev & Tinsley, 2024). Moreover, studies on specific populations, such as pharmacy students preparing didactic patient presentations, reveal that while GenAI effectively organizes clinical information and improves student confidence, its success heavily depends on the user's prior experience and domain knowledge (Baker et al., 2024). Furthermore, students report anxieties regarding the potential loss of their authentic voice and the dilution of human emotion in their presentations, which are critical for effective audience engagement (Chu et al., 2025; Kim et al., 2024). Consequently, a shared finding across studies is that while students readily delegate routine preparatory tasks to GenAI, they strongly prefer to retain human oversight and control over the final presentation to ensure authenticity and logical rigor.

2.3. Student Evaluations of GenAI through the Technology Acceptance Model

To systematically understand students' adoption of GenAI, researchers have frequently relied on the Technology Acceptance Model (TAM), originally developed by Davis (1989), which posits Perceived Ease of Use (PEOU) and Perceived Usefulness (PU) as the primary drivers of technology acceptance (King & He, 2006). In the context of GenAI, studies highlight that personal innovativeness, habit, and hedonic motivation significantly predict students' behavioral intention to utilize tools like ChatGPT (Strzelecki, 2023). The conversational and intuitive interfaces result in exceptionally high PEOU evaluations, as students find the barrier to entry remarkably low (Ngo, 2023). The ease with which students can enter prompts, adjust outputs, and interact with the AI significantly bolsters their behavioral intention to continue using these technologies for academic tasks (Strzelecki, 2023).

Conversely, student evaluations of Perceived Usefulness (PU) present a more paradoxical picture. On one hand, students highly rate the immediate benefits of GenAI, such as rapid task completion, enhanced writing quality, and the provision of immediate, personalized feedback (Chan & Hu, 2023; Kim et al., 2024). On the other hand, this perception of usefulness is frequently counterbalanced by profound concerns over academic integrity, algorithmic bias, and the reliability of AI-generated content (Dwivedi et al., 2023; Perkins, 2023). Students are especially aware of the phenomenon of AI "hallucinations"—the generation of plausible but factually incorrect information and fabricated citations—which directly threatens the rigorous standards required in higher education (Kim et al., 2024; Ngo, 2023). Furthermore, a significant debate exists regarding the long-term impact of GenAI on holistic competency development. While students appreciate the short-term productivity gains, they simultaneously express concern that an over-reliance on AI may hinder their independent critical thinking, problem-solving skills, and social interaction skills (Chan & Hu, 2023; Chu et al., 2025). This suggests that students view GenAI in a practical way. Students appear to value GenAI primarily for its immediate contribution to task efficiency, while remaining less certain about its role in deeper competence development.

While the existing literature offers a strong foundation for understanding the general adoption, perceived benefits, and ethical concerns surrounding GenAI in higher education, an important research gap remains. Much of the current literature has focused on traditional academic writing or broad patterns of use, rather than examining how students allocate specific tasks to GenAI within complex, multimodal assignments such as academic presentations. Furthermore, empirical data exploring the relationship of perceived usefulness and ease of use in these specific, design-oriented contexts is limited. The present study addresses this identified gap by systematically examining undergraduate students' self-reported use of GenAI for academic presentation design. By investigating their nuanced usage patterns, specific task delegation practices, and detailed evaluations of GenAI tools, this study contributes essential empirical insights into how students navigate the intersection of human creativity and artificial intelligence in modern higher education.

3. Methodology

3.1 Participants and Procedure

Participants were 197 undergraduate students enrolled at a Vietnamese university in Ho Chi Minh City during the 2025–2026 academic year. The sample comprised 131 female (66.5%) and 65 male (33.0%) students, with one participant identifying as they/them (0.5%); one response was excluded from the initial 198 due to an uninterpretable entry. Participants were predominantly third-year students (n = 127, 64.5%), with second-year (n = 60, 30.5%) and fourth-year-or-above (n = 10, 5.1%) also represented. Data were collected via a Google

Forms survey using the convenience sampling method. Participation was voluntary and anonymous; no personally identifying information was collected.

3.2. Instrument

The study collected data through a survey that consisted of four sections. The first collected demographic and background information, including year of study, gender, prior AI experience, and frequency of AI use for presentation preparation. The second examined usage patterns, covering the purposes of AI use, types of AI tools employed, the proportion of work delegated to AI, and disclosure practices. The third explored students' attitudes, including their perceived ability to complete presentations without AI, awareness of citation and attribution norms for AI-assisted work, and perceived changes in presentation skills since adopting AI. The fourth section comprised 5-point Likert-scale items based on the Technology Acceptance Model (TAM) and its subsequent extensions. Adapted from the foundational work of Davis (1989), the TAM2 framework by Venkatesh and Davis (2000), and the Unified Theory by Venkatesh et al. (2003), this section was contextualized for GenAI. It measured three core constructs: Perceived Usefulness, Perceived Ease of Use, and Behavioral Intention to continue using GenAI for future academic presentations.

3.3. Measurement Validation

All analyses were conducted using IBM SPSS Statistics. Before addressing the research questions, the three TAM-based constructs were examined to confirm that the survey items were appropriate and reliable. The results showed that the items were suitable for factor analysis and formed a clear three-factor structure, explaining 71.4% of the total variance. The three scales also demonstrated good reliability: Perceived Usefulness ($\alpha = .79$, $M = 3.94$, $SD = .67$), Perceived Ease of Use ($\alpha = .91$, $M = 4.00$, $SD = .74$), and Behavioral Intention ($\alpha = .91$, $M = 4.14$, $SD = .82$). In addition, the data met the basic assumptions for further statistical analysis. Composite scores were then calculated by averaging the items within each construct, and these scores were used in the subsequent analyses.

4. Results

4.1 Research Question 1: Usage Patterns and Task Delegation

RQ1 examined the current usage patterns and levels of task delegation when undergraduate students employ GenAI for presentation design. This question was addressed through three analytic steps: (a) descriptive analysis of usage intensity, (b) multiple-response analysis of purposes and tools, and (c) K-means cluster analysis to identify user typologies. Following established methodological precedents in educational AI research (Luckin et al., 2022), this clustering approach was used to segment students into three distinct behavioral profiles—Power Integrators, Selective Minimalists, and Skeptical Delegators—facilitating a targeted analysis of their task delegation strategies.

4.1.1 Intensity and Modes of GenAI Use

Descriptive analyses revealed that GenAI has become a routine component of presentation preparation rather than an occasional aid. As Table 1 shows, **86.8% of participants reported using GenAI at least weekly**, with 43.7% using it daily. Only 4.1% reported rare or no use. This frequency distribution meaningfully exceeds the adoption levels reported in previous empirical studies (e.g., Chan & Hu, 2023; Strzelecki, 2023), suggesting that within this sample, GenAI use was highly common.

Table 1

Frequency Distribution of Usage Intensity, Delegation, and Perceived Outcomes (N = 197)

Variable	Response option	n	%
Usage frequency	Never / rarely	8	4.1
	Monthly (1–3×/month)	18	9.1
	Weekly (1–3×/week)	85	43.1
	Daily (≥ 1×/day)	86	43.7
Delegation (% workload by AI)	0–25%	26	13.2
	26–50%	116	58.9
	51–75%	44	22.3
	76–100%	11	5.6
Disclosure of AI use	Yes	92	46.7
	No	27	13.7
	Have not considered	78	39.6
Self-rated skill change	Significantly decreased	1	0.5
	Slightly decreased	4	2.0
	No change	50	25.4
	Increased slightly	96	48.7
	Increased significantly	46	23.4

Although students reported frequent use of GenAI, the data suggest that they used it mainly as a support tool rather than as a replacement for their own work. Most students (58.9%) said GenAI contributed between 26% and 50% of their presentation workload, while heavy delegation was uncommon, with only 5.6% reporting AI involvement at the 76–100% level. Minimal delegation was also relatively low at 13.2%. This pattern challenges the common concern about widespread "AI over-reliance" in education, as students appeared to retain substantial control over the final product. However, their disclosure practices were less consistent. While 46.7% reported openly acknowledging AI use, only 13.7% reported not disclosing it, and a large proportion, 39.6%, had not considered disclosure at all. This suggests that many students may lack clear guidance on AI attribution, pointing to a need for stronger institutional policy and curriculum support (Perkins, 2023). At the same time, students generally viewed GenAI as beneficial for their development, with 72.1% reporting slight or significant improvement in presentation skills and only 2.5% reporting decline. Overall, the findings present a balanced picture: students used GenAI frequently, but mostly in a controlled and supportive way, while issues of disclosure and academic guidance remain underdeveloped.

4.1.2 Purposes and Tools: An Asymmetric Delegation Pattern

Multiple-response analysis revealed a distinctive asymmetry in how students distribute AI assistance across the presentation workflow (Table 2). Preparation-stage tasks were extensively delegated: 93.4% of participants used AI for content preparation. In contrast, performance-stage tasks remained largely human-driven: only 34.0% used AI during the live presentation itself. Design (49.2%) and practice/feedback (41.6%) occupied intermediate positions in this gradient.

Table 2

Multiple-Response Frequencies for Purposes and Tools (N = 197)

Category	Option	n responses	% of responses	% of cases
Purposes of GenAI use	Content preparation	184	42.8	93.4
	Presentation design	97	22.6	49.2
	Practice / feedback	82	19.1	41.6
	Live presentation	67	15.6	34.0
Tools used	Content generators	191	47.6	97.0
	AI search	103	25.7	52.3
	Slide creators	68	17.0	34.5
	Image generators	21	5.2	10.7
	Video generators	17	4.2	8.6
	Other	1	0.2	0.5

Note. Percentages of cases sum to more than 100 because participants could select multiple options.

Students showed a clear difference in how they used AI across presentation tasks. They seemed more willing to use AI for preparation work, such as generating ideas, organizing content, and drafting text, but they kept more control over the actual performance stage, such as speaking in front of an audience. This pattern aligns with recent findings that students prefer to use AI for structural preparation while retaining human oversight and control over final presentation outcomes (Georgiev & Tinsley, 2024). It also gives a more balanced view than the common concern about AI over-reliance. Rather than using AI for everything, students appeared to make careful choices about when AI support was useful and when they needed to rely on themselves.

A similar pattern appeared in the types of tools students used. Text-based GenAI tools were the most common, with 97.0% using content generators such as ChatGPT, Gemini, or DeepSeek, and 52.3% using AI-powered search tools. In contrast, fewer students used multimodal tools: 34.5% used slide creation tools such as Gamma or Tome, 10.7% used image generators such as Midjourney or DALL-E, and 8.6% used video generators such as Synthesia or Runway. This suggests that students did not simply adopt every kind of AI tool available. Instead, their use followed a text-first pattern, probably because academic presentations depend heavily on research, writing, and script preparation. Practical issues such as cost, difficulty of use, and unclear relevance may also explain why multimodal tools were less widely used.

4.1.3 User Typology: Three GenAI Adopter Profiles

Although the descriptive results showed that GenAI adoption was generally high, they did not fully show the differences in how students used these tools. To examine these differences more clearly, a K-means cluster analysis was conducted using six standardized indicators: usage frequency, delegation percentage, number of presentation stages using AI, number of AI tool categories used, perceived dependence on AI, and perceived usefulness. The analysis found that a three-cluster solution was the clearest and most balanced. All six variables showed significant differences across the clusters, with F values ranging from 21.34 to 59.96, all $p < .001$, and η^2 values from .18 to .38, indicating medium-to-large effects. Other options, including four-cluster and TwoStep solutions, were also tested, but they were either less balanced or less meaningful in explaining the data.

The three clusters differed systematically across behavioral and attitudinal indicators, as shown in Table 3. They were interpreted as distinct adopter profiles and labeled accordingly: *Power Integrators*, *Selective Minimalists*, and *Skeptical Delegators*.

Table 3

Profile of the Three GenAI User Clusters (N = 197)

Indicator	Cluster 1: Power Integrators (n = 84, 42.6%)	Cluster 2: Selective Minimalists (n = 72, 36.5%)	Cluster 3: Skeptical Delegators (n = 41, 20.8%)	F(2, 194)	p
Usage frequency (1–5)	4.65	3.99	3.93	21.34	< .001
Delegation band (1–4)	2.54	1.79	2.24	24.79	< .001
N presentation stages (0–4)	2.73	1.49	2.29	42.60	< .001
N tool categories (0–6)	2.80	1.33	1.71	50.60	< .001
Can complete without AI (1–5)	3.11	3.72	2.51	30.17	< .001
Perceived Usefulness (1–5)	4.32	3.90	3.19	59.96	< .001
Perceived Ease of Use (1–5)	4.28	3.95	3.51	18.76	< .001
Intention to continue use (1–5)	4.55	4.01	3.54	28.28	< .001

The cluster results suggest that students did not use GenAI in one single way. Instead, their use formed three clear patterns, ranging from broad and confident integration to more limited or uneasy use. The largest group was the Power Integrators (n = 84, 42.6%). These students showed the strongest level of GenAI adoption. They used GenAI most frequently (M = 4.65), almost at the level of daily use, and applied it across more presentation stages than the other groups (M = 2.73 out of 4). They also used the widest range of tools (M = 2.80 out of 6). What makes this group stand out is their use of multimodal tools. Compared with the full sample, they were much more likely to use slide-creation tools (63% vs. 34.5%), AI search tools (81% vs. 52.3%), and image generators (19% vs. 10.7%). Their attitudes were also the most positive, with the highest scores for perceived usefulness (M = 4.32), perceived ease of use (M = 4.28), and intention to continue using GenAI (M = 4.55).

A second group, the Selective Minimalists (n = 72, 36.5%), used GenAI in a much more careful and limited way. They were not avoiding AI, but they did not spread their use across many tools or tasks. Most of them used it for content preparation, with 88% reporting this purpose. However, only 7% used slide creators, and only 28% used AI search tools. This group also reported the strongest sense of independence, with the highest score for being able to complete a presentation without AI (M = 3.72). Their workload delegation was the lowest (M = 1.79), mainly falling within the 0–25% range. Even so, their views of GenAI were still generally positive, as shown by their perceived usefulness score (M = 3.90) and intention to continue using it (M = 4.01). This suggests that they were not skeptical users. Rather, they seemed to set boundaries around AI use and kept it mainly as a support tool.

The smallest group, the Skeptical Delegators (n = 41, 20.8%), showed the most complicated pattern. These students seemed to rely on GenAI, but they did not evaluate it as positively as the other groups. They had the lowest autonomy score (M = 2.51), suggesting that they found it difficult to complete presentations without AI. At the same time, they also had the lowest scores for perceived usefulness (M = 3.19), perceived ease of use (M = 3.51), and intention to continue using GenAI (M = 3.54). This creates a somewhat uneasy profile: they appear to need AI, but they are not fully comfortable with it or convinced of its value. For

teaching practice, this group may be especially important because they may need more guidance on how to use GenAI with clearer purpose, less dependence, and greater confidence.

4.2 Research Question 2: Students' Perceptions of GenAI Usefulness and Ease of Use

RQ2 examined how students perceive the usefulness and ease of use of GenAI tools for academic presentations. At the construct level, students showed generally positive views of both TAM dimensions. The mean score for Perceived Usefulness was relatively high, PU *(M = 3.94, SD = .67)*, and the mean score for Perceived Ease of Use was also high, PEOU *(M = 4.00, SD = .74)*. Since both scores were above the scale midpoint of 3.00, the results suggest that students generally found GenAI useful and easy to use. However, the scores were not extremely high, which means students' views were positive but not overly idealized. In other words, they appeared to recognize the value of GenAI while still leaving room for some caution or critical judgment. A closer look at the individual items provides a more detailed picture of how students understood GenAI's usefulness and ease of use.

Table 4

Item-Level Descriptive Statistics for PU and PEOU (N = 197)

Construct	Item	Item content	*M*	*SD*
PU	PU1	AI helps me complete presentations faster	**4.29**	.82
	PU2	AI improves content / idea quality	4.25	.82
	PU4	I am satisfied with AI suggestions / content	3.68	.85
	PU6	My presentation skills have clearly improved with AI	**3.54**	.95
PEOU	PEOU1	Easy to learn how to interact with AI	3.94	.78
	PEOU2	Entering prompts and adjusting outputs is not complex	4.06	.91
	PEOU4	Using AI is intuitive and quick	3.94	.78
	PEOU5	I easily understand and adjust AI-generated content	4.08	.87

The PU items suggest what this study calls a productivity-development asymmetry. Students gave the strongest support to items related to immediate task completion. For example, PU1, "AI helps me complete presentations faster," had the highest mean score *(M = 4.29)*, followed closely by PU2, "AI improves content / idea quality" *(M = 4.25)*. In contrast, the item related to longer-term skill growth, PU6, "my presentation skills have clearly improved," received the lowest mean score *(M = 3.54)*. The difference between PU1 and PU6 was 0.75 points, which is meaningful on a 5-point scale. This suggests that students mainly understand GenAI's usefulness in terms of saving time and improving the quality of the immediate product, rather than helping them gradually develop their own presentation skills. In practical terms, students seem to value what AI helps them produce more than what AI helps them learn. This distinction is important for how teachers design and explain AI-assisted assignments, as discussed in Section 5.

The PEOU items showed a more even pattern, with mean scores ranging from 3.94 to 4.08. This means that students generally found GenAI easy to use across different stages, including learning how to use it, writing prompts, interacting with the tool, and editing its output. The highest-rated item was PEOU5, "I easily understand and adjust AI-generated content" *(M = 4.08)*. This suggests that students felt confident not only in using GenAI, but also in reviewing and modifying what it produced. Therefore, based on their self-reported ease of use, students did not see themselves as simply accepting AI-generated content passively.

Rather, they appeared to see themselves as active editors who could adapt AI output to fit their own presentation needs.

5. Discussion

5.1 Adoption Intensity

The finding that 86.8% of students used GenAI at least weekly, with 43.7% using it daily, suggests that GenAI has become a routine part of academic presentation preparation in this sample. However, frequent use did not necessarily mean full dependence. Most students reported that AI contributed only 26–50% of their presentation workload, while very high delegation remained uncommon. This indicates that students generally used GenAI as a support tool rather than as a complete substitute for their own work.

At the same time, the findings show a gap between adoption and responsible-use awareness. Although 46.7% of students reported disclosing AI use, 39.6% had not considered disclosure. This suggests that students may be using GenAI more quickly than they are developing clear understandings of attribution and academic integrity. Therefore, the main pedagogical issue is no longer whether students use GenAI, but how well they are guided to use it transparently, critically, and appropriately.

5.2. The User Typology

The identification of three distinct user profiles including Power Integrators, Selective Minimalists, and Skeptical Delegators demonstrates that students are not a uniform group. This suggests that the quality of engagement can vary independently from the quantity of use, a pattern that would be missed if the study only reported overall adoption rates. The differences among these groups are particularly revealing when examining how students balance AI assistance with their own academic autonomy. For instance, the Skeptical Delegators cluster highlights a particularly vulnerable subgroup of learners. These students report lower autonomy in their ability to complete presentations without AI, while simultaneously evaluating GenAI tools less positively. They may therefore be interpreted as dependent but less confident users. Because they appear to rely on the technology without being fully convinced of its value or ease of use, this group underscores the necessity of targeted pedagogical interventions. Educators must provide these students with structured practice to build both their independent presentation skills and their digital confidence.

This pattern is consistent with broader concerns in the literature that some students may rely on AI without fully trusting or valuing it. Their needs are unlikely to be addressed by either general pro-AI messages or strict usage restrictions, since they are not highly enthusiastic but also feel unable to avoid AI. Future longitudinal research could examine whether students' GenAI engagement develops from limited use toward broader and more confident integration. This has important implications for curriculum design, as early AI literacy support may influence the kind of GenAI engagement pathway students eventually develop.

5.3. Students' Evaluation of GenAI Usefulness and Ease of Use

The findings show that students evaluated GenAI positively in terms of both perceived usefulness and perceived ease of use. Both construct means were above the scale midpoint, suggesting that students generally found GenAI helpful and manageable for academic presentation preparation. However, the item-level results show an important distinction. Students rated GenAI most highly for helping them complete presentations faster and improve content or ideas. In contrast, they gave a lower rating to the item about whether AI clearly

improved their own presentation skills. This suggests that students valued GenAI more for immediate productivity than for long-term skill development.

The study's findings regarding students' evaluations of Perceived Usefulness can be further understood through the extended Technology Acceptance Model (TAM2) proposed by Venkatesh and Davis (2000). According to their theoretical framework, users form usefulness judgments through cognitive instrumental processes, consciously comparing what a technology is capable of doing with what they specifically need to achieve. In this study, students appeared to value GenAI mainly for practical support, especially speed and content improvement. However, their lower rating for presentation-skill development suggests that they may not view AI assistance as equally valuable for deeper learning growth. This distinction indicates that GenAI may support task completion more readily than skill development unless educators design activities that require reflection, revision, and critical evaluation of AI-generated output.

5.4. Pedagogical Implications

The findings suggest several implications for GenAI integration in academic presentation tasks. First, because students already use GenAI frequently, educators should provide clearer guidance on appropriate task delegation, output evaluation, and disclosure of AI assistance. Second, assessment design should recognize students' tendency to use AI more for preparation than for live performance by combining AI-supported preparation tasks with authentic oral delivery, explanation, and Q&A. Third, the three user profiles indicate that students may need differentiated support. Power Integrators may benefit from advanced guidance on critical evaluation and responsible multimodal use, while Selective Minimalists may need support in expanding effective uses of AI without weakening autonomy. Skeptical Delegators may require more structured practice to build confidence and reduce unreflective dependence. Finally, the gap between productivity gains and perceived skill development suggests that AI-assisted assignments should include reflection and revision activities so that students can connect AI use with learning growth rather than task completion alone.

5.5. Limitations

Several limitations should be considered when interpreting the findings. First, the study used a cross-sectional design, so it cannot establish causal relationships among AI use, perceived usefulness, ease of use, and intention to continue use. Second, the data were based on self-reported survey responses, which may not fully reflect students' actual AI practices, prompt behavior, or presentation performance. Third, the sample was drawn from one Vietnamese university, limiting the generalizability of the findings to other institutional, disciplinary, or cultural contexts. Fourth, the Behavioral Intention construct was measured with only two items, which may limit its conceptual coverage despite acceptable reliability. Finally, the K-means clustering results should be interpreted as exploratory, as cluster solutions can be sensitive to sample characteristics and require validation with independent datasets. Future studies should use longitudinal, mixed-method, or performance-based designs to examine how GenAI use affects presentation development over time.

6. Conclusion

This study examined undergraduate students' self-reported use of GenAI for academic presentation design and their evaluations of its usefulness and ease of use. The findings show that GenAI has become a routine support tool in students' presentation preparation, particularly for content-related tasks. However, frequent use did not necessarily indicate full dependence, as most students reported only moderate levels of task delegation and retained greater control over performance-related activities.

The study also shows that students are not a homogeneous group of GenAI users. The three profiles, Power Integrators, Selective Minimalists, and Skeptical Delegators, suggest that students differ in usage frequency, task delegation, tool diversity, perceived autonomy, and attitudes toward GenAI. In addition, students valued GenAI more strongly for immediate productivity and content improvement than for long-term presentation skill development.

These findings highlight the need for pedagogically guided GenAI integration in higher education. Rather than focusing only on whether students use AI, educators should support students in using it transparently, critically, and purposefully. AI-assisted presentation tasks should therefore include clear guidance on disclosure, appropriate delegation, output evaluation, and reflective revision, so that GenAI use contributes not only to task completion but also to students' academic and communicative development.

#58 ASSESSING THE EFFECTIVENESS OF QUIZIZZ IN IMPROVING VOCABULARY LEARNING OF EFL FRESHMEN STUDENTS AT HUFLIT

LÊ THY PHƯƠNG THẢO

Abstract

Gamified learning instruments have received considerable focus in language teaching, especially in vocabulary development. This research examines the effectiveness of Quizizz in improving vocabulary acquisition among freshmen EFL learners at HUFLIT. Employing a combination of methods, information was gathered from 100 students via surveys and evaluations to assess the effect of Quizizz on students' enthusiasm, participation, and vocabulary retention. The results show a significant link between the use of Quizizz and increased student excitement, engagement, and academic outcomes. Nonetheless, constraints like monotonous question structures and the absence of customized learning pathways were noted. The research indicates that combining multimedia components, various question formats, and personalized learning capabilities could improve the platform's efficiency. These results underscore the significance of learning powered by technology strategies and offer perspectives for learners looking to enhance digital resources for vocabulary.

***Keywords*:** Gamified learning, Quizizz, vocabulary acquisition, EFL freshmen students, motivation, technology-enhanced learning, digital tools in education.

1. Introduction

1.1 Background

English vocabulary is essential for communication and professional success in today's globalized society. The need for creative and engaging ways to improve vocabulary learning continues to grow as English proficiency becomes increasingly crucial. Freshmen HUFLIT students who are prepared for their future occupations frequently struggle to stay motivated and successfully retain language using conventional approaches. This emphasizes the need for more effective and interactive educational resources. Quizizz, a gamified learning platform used in education to make learning more engaging and enjoyable, has seen increased popularity in recent years. However, its precise effect on enhancing freshmen HUFLIT students' vocabulary acquisition, particularly in terms of preparing them for professional contexts, remains an important topic of research. To fulfill the growing need for efficient vocabulary learning solutions for these students, this study looks at how Quizizz handles these difficulties.

1.2 Literature Review

To improve learning, English language teaching has undergone substantial change, utilizing cutting-edge resources and techniques (Harmer, 2007). These include e-learning programs like Quizizz, which have become well-known by allowing teachers to design popular online tests (Degirmenci, 2021, & Hidayati, 2019). A dynamic learning environment is promoted by Quizizz's game-like features, which encourage rivalry and engagement among students (Pagnattaro, 2017). Furthermore, Quizizz has been demonstrated to boost vocabulary acquisition through games, repetition, and images that enhance comprehension, pronunciation, and memorization (Nguyen Thi Huong, 2024). According to Hussain et al. (2023), as mentioned in Law et al. (2021), educational tools like Quizizz, Schoology, and Kahoot are commended for increasing motivation, interaction, prompt feedback, and overall learning efficiency. Additionally, interest is a vital learning catalyst that encourages people to commit

time and energy to their academic endeavors (Mesterjon et at., 2024, as referenced in Ratnasari, 2021).

1.3 Objectives

The purpose of the study is to determine how well Quizizz helps freshmen HUFLIT students acquire vocabulary and to make recommendations for methods to improve their motivation, retention, and preparedness for professional use. The results of a study carried out at HUFLIT to ascertain how Quizizz affects vocabulary acquisition and its function in preparing students for future occupations are presented in this research. This study's objective was to examine the effects of Quizizz on students' vocabulary acquisition, emphasizing quantifiable gains in their interest and performance. This thesis investigates whether Quizizz can help HULFIT freshmen students acquire the specific vocabulary required for success in both the classroom and the workplace.

1.4 Research Question

To ensure that the research corresponds to the aim, the study is guided by the following research question: In what way does Quizizz contribute to the vocabulary learning of EFL freshmen students of HUFLIT?

1.5 Scope

The present paper is devoted to the use of Quizizz by HUFLIT freshmen students for vocabulary learning. It evaluates the degree to which Quizizz helps to engage students and improve their vocabulary acquisition results. The study involves 100 freshmen EFL students who have been using Quizizz in vocabulary-learning activities before. The research takes place during March and April 2026, thus providing a time frame for data gathering and analysis. The possible biases in self-reported data and the differences in participants' previous experiences with gamification platforms such as Quizizz are some limitations of the study.

1.6 Organization

The present paper is structured into five main sections. The first section includes an introduction, aim, research questions, scope, and organization of the study. The second one reviews the literature related to vocabulary learning, gamified learning, and the application of Quizizz in the EFL context. The third section provides information about research design, participants, data-gathering tool, procedure, and statistical treatment of data. The fourth section states the results concerning the effectiveness of Quizizz, students' engagement, helpful features, and challenges. The fifth section contains a discussion of results, limitations, implications, and recommendations.

2. Literature review

2.1 Vocabulary Learning

Since vocabulary is the basis for both successful communication and the development of other language abilities, it is essential for language learning. To improve vocabulary acquisition, Harmer (2007, p.229) highlights that students should study words in context and comprehend both their meaning and structure. Improving vocabulary development is still a major goal in English language programs, especially at the fundamental level, because of its significance. Understanding spoken and written language requires a strong vocabulary (Boyinbode, 2018). Learners find it difficult to understand and effectively communicate concepts when they are unaware of word definitions.

According to Afzal (2019), vocabulary is essential for language acquisition and communication. He points out that students' vocabulary acquisition and academic performance can be greatly improved by employing cognitive and metacognitive techniques in addition to providing learning opportunities. Ghalebi et al. (2021) stated that vocabulary development is crucial for learning a foreign language since vocabulary difficulties can impede communication and reading comprehension, especially for non-native English speakers.

Yawiloeng (2020) emphasizes once more how important vocabulary acquisition is to the development of fundamental language abilities, such as speaking, listening, reading, and writing. Teachers must use efficient teaching techniques to get students interested in acquiring language. According to Teng (2019), the objective of vocabulary learning is for students to commit new words to memory and use them in a variety of conversational scenarios. However, because vocabulary must be actively used in productive abilities like speaking and writing, some students find this process tiresome because of the demands of memory and repetition.

Early exposure to new words greatly improves language development; therefore, young learners must master vocabulary (Ramadhan & Zaharani, 2021). Vocabulary acquisition should be given top priority to promote general language competency and fluency.

2.2 Significance of Vocabulary Learning in English

Before they may utilize new words in speech and improve their language skills, learners must be exposed to them repeatedly through listening (Rowe, 2012). Thus, it is essential to teach vocabulary in the early stages of language learning (Schmitt, 2010). To put it another way, to demonstrate their language skills, learners need to get familiar with a particular collection of vocabulary. It would be challenging to communicate thoughts and comprehend others without a large vocabulary.

By increasing their productive vocabulary, English language learners can develop their communication abilities and achieve fluency and clear expression in the target language. Kilic (2019) discovered that among English as a foreign language learners, vocabulary knowledge is a strong predictor of speaking and writing performance, underscoring the significance of increasing vocabulary to improve communication abilities. This implies that having a strong vocabulary not only makes comprehension easier, but it is also essential for students to be able to express themselves clearly both orally and in writing.

2.3 Challenges in Vocabulary Learning

Even though studying vocabulary is crucial to learning English as a foreign language (EFL), many students encounter a variety of challenges. These difficulties include learning new words, pronouncing, using, spelling, and memorizing them correctly (Afzal, 2019). Additionally, acquiring synonyms, distinguishing words with numerous meanings, and appropriately utilizing prefixes and suffixes memorizing them (Afzal, 2019, p. 81). Additionally, acquiring synonyms, distinguishing words with numerous meanings, and appropriately utilizing prefixes and suffixes are all challenges that EFL students frequently face (Khan, 2011, p. 1255).

Errors among university students have also been noted in other research (Abdulaal, 2019; Sheir et al., 2016), especially confusion brought on by near-synonyms and similar spellings. These results show that EFL learners continue to struggle with vocabulary acquisition, which impedes their overall language ability. Given the significance of language acquisition, academics have looked for novel ways to improve instruction beyond conventional techniques. Vocabulary education is one of the new instruments for English language teaching

brought about by technological advancements. Multimedia software can be included in language instruction to enhance vocabulary acquisition (Astika, 2014).

Recent advancements in technology offer teachers and students unmatched opportunities for vocabulary acquisition (2017, p.45). By boosting student involvement and offering relevant settings for word comprehension, digital tools and media can improve vocabulary learning (Hermagustiana & Resmawaty, 2017, p. 138). In response to these issues, this study looks at how educational apps like Quizizz can help EFL students acquire vocabulary more effectively.

2.4 Quizizz's Effects on Freshmen's Motivation and Participation in Vocabulary Learning

The millennial generation, which is strongly associated with technology and contemporary developments, is particularly affected by this problem. Gamification has become a successful tactic in language classes, and integrating technology into language learning is essential for closing this gap (Medina & Hurtado, 2017).

As a digital learning tool, gamification is flexible and provides individualized feedback based on the requirements of every student. It facilitates differentiated instruction and aids in students' vocabulary acquisition through repetition and context (Abrams & Walsh, 2014). Quizizz is one such gamified tool that enables educators to design captivating, creative, and interactive lessons using kinesthetic and audiovisual components (Aini, 2019).

Teachers can increase student motivation and engagement by integrating Quizizz into vocabulary instruction, which will make learning more pleasurable and productive. Quizizz is an effective teaching tool that uses gamification to improve vocabulary acquisition in English. Its dynamic and captivating features are intended to inspire students and encourage their engagement with the material covered in class.

In contrast to conventional formative assessments, Quizizz offers a fun and competitive setting that discourages cheating while enhancing the learning experience (Amalia, 2020). Additionally, it helps teachers evaluate students' language skills and curriculum comprehension (Bury, 2017).

Quizizz's game-based features, which include avatars, themes, memes, and music, are one of its main characteristics that make studying entertaining and interesting. By reviewing vocabulary interactively, students can increase their engagement and recall (Pavita & Nirmala, 2021). Quizizz is a fun way to kill time. Students may learn at any time and from any location thanks to the platform's accessibility on a variety of platforms, including PCs, laptops, tablets, and smartphones.

Students can find errors and strengthen their vocabulary by using the platform's instant feedback (Nhu & Tin, 2019). According to research, students feel favorably about utilizing Quizizz as an online assessment tool, especially for formative tests (Pusparani, 2021). Quizizz also provides teachers with comprehensive information, such as reports at the class and student levels that may be saved as Excel files for additional analysis.

2.5 Advantages of Using Quizizz

Quizizz has several advantages for teaching and studying English, especially when it comes to grammatical comprehension, motivation, and self-evaluation. Rahayu and Purnawarman (2019) claim that Quizizz helps students evaluate their strengths and weaknesses, thereby enhancing their academic performance through frequent tests,

evaluations, and feedback. According to Razali et al. (2020), Quizizz's gamification features are essential for encouraging students' internal and extrinsic motivations.

Bal (2018) found that Quizizz improves vocabulary retention more effectively than conventional approaches. Similarly, Quizizz greatly enhances grammar learning, increasing the effectiveness of knowledge acquisition, according to Dewi et al. (2020). Additionally, according to Lestari's (2019) comparison of Quizizz and Kahoot, students prefer Quizizz because of its better levels of engagement, challenge, and incentive. Additionally, Quizizz encourages students to adopt a more proactive approach to learning by creating a positive washback effect, according to Pitoyo et al. (2020).

Overall, research results confirm that Quizizz is not only a useful instrument for teaching English but also a strong motivator that improves students' vocabulary and grammatical acquisition while fostering an interesting and fruitful learning environment.

2.6 Disadvantages of Using Quizizz

Quizizz has drawbacks despite its many benefits. One disadvantage is that students' scores may be impacted by how quickly they complete the test; the quicker they respond, the higher their scores, which might not necessarily accurately represent their comprehension. Furthermore, Quizizz is dependent on a reliable internet connection; if the connection is poor and unreliable, students may be locked out, which can lead to lost progress.

The fact that some advanced functions, including embedding instructional films, need a premium subscription is a major drawback for educators. This might prevent the full potential of the free version. Internet dependence is a significant obstacle to adopting Quizizz as an assessment tool.

Education has been greatly impacted by the growing availability of the Internet in homes, companies, and educational institutions. Research shows that students' ability to access online material has a significant impact on their academic achievement. Smartphones are becoming the most common way to access the Internet, which facilitates easy contact among academics and supports learning, research, and assignment completion.

3. Methodology

3.1 Overview

This study examines how well Quizizz helps freshmen EFL students at HUFLIT learn vocabulary and how it relates to their future employment. To fully comprehend students' learning experiences, a mixed-methods approach was used, combining quantitative and qualitative data. A questionnaire that evaluated vocabulary learning difficulties, students' involvement with Quizizz, and their opinions of its efficacy served as the main instrument for gathering data.

3.2 Sampling Technique

Convenience sampling was used since it is a realistic way to effectively reach a large number of individuals. One hundred HUFLIT freshmen EFL students were chosen to take part in this study. Students who actively participated in Quizizz vocabulary-learning activities were chosen as participants. Although the results' generalizability was restricted by the convenience sampling technique, it offered insightful information on the experiences of a particular set of students.

3.3 Sample Restriction

To ensure consistency in language proficiency, the study specifically targeted freshmen EFL students at the intermediate level. Students who were not actively involved in vocabulary learning with Quizizz were excluded from the study to maintain reliability in data collection and analysis. By focusing on this specific group, the study aimed to provide accurate and meaningful insights into the effectiveness of Quizizz in vocabulary acquisition.

3.4 Materials

A structured questionnaire built with Google Forms served as the study's main method of data collection. Each of the four sections of the questionnaire was intended to cover a different facet of the study. Name, age, and gender were among the demographic information gathered in the background information section. Multiple-choice questions were used in the second part. The third section, Engagement with Quizizz, utilized Likert-scale items to evaluate students' motivation and interaction levels. The fourth section, Perceived Effectiveness of Quizizz, featured rating scales and open-ended questions to gather insights into students' experiences and opinions on how Quizizz contributed to their vocabulary learning. Before distribution, the questionnaire underwent a review process to ensure clarity, reliability, and relevance.

3.5 Procedure

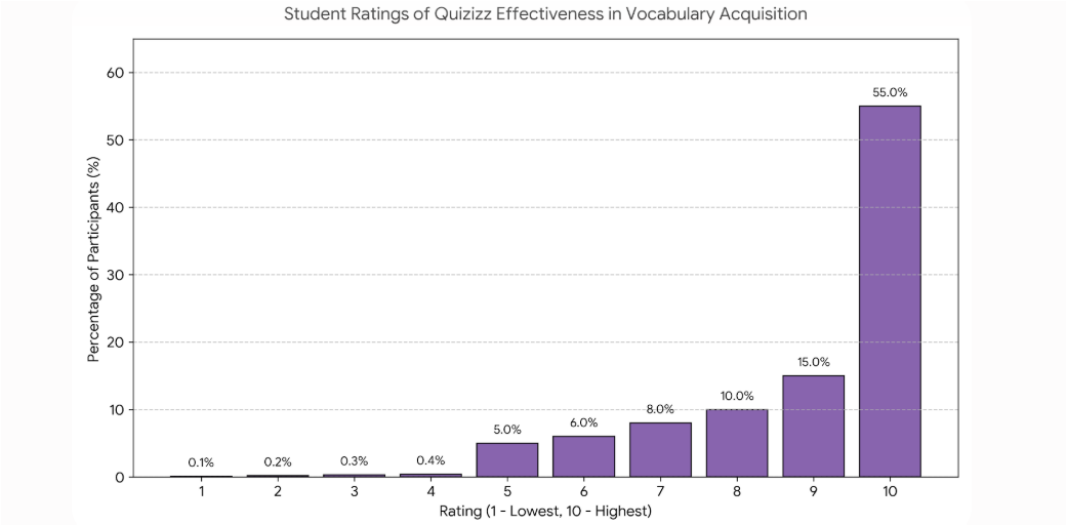
The research was conducted systematically in several stages to ensure a thorough investigation into the impact of Quizizz on vocabulary acquisition. The study was carried out from March to April of 2026, during which data collection took place. The first stage involved questionnaire design and validation. The research team carefully constructed the survey, ensuring that the questions aligned with the study's objectives. Once completed, the questionnaire was reviewed by language educators and peers to confirm its clarity and relevance. In the second stage, the distribution of the questionnaire, the finalized survey was shared with participants via a private online group of students. Participants were given detailed instructions on how to complete the questionnaire, ensuring that they understood each question type, including multiple-choice questions, Likert-scale items, rating scales, and open-ended responses. Students were allocated 5-6 minutes to complete the survey at their convenience. The third stage focused on data collection and monitoring. The research team monitored responses to ensure a sufficient number of completed questionnaires. The participation rate was observed daily, and reminders were posted in the online group to encourage full engagement. After reaching the target number of responses, the final stage involved data compilation and preparation for analysis. In April 2026, the questionnaire was closed, preventing further submissions. The collected responses were then organized, cleaned, and prepared for statistical and thematic analysis. By following this structured procedure, the study ensured the reliability and validity of the data collected.

3.6 Statistical Treatment

A combination of quantitative and qualitative analysis methods was applied to analyze the collected data. Quantitative responses, including multiple-choice and Likert-scale items, were analyzed using descriptive statistical techniques such as frequency distribution, mean scores, and percentage analysis. This approach provided numerical insights into students' engagement levels,

learning experiences, and perceived effectiveness of Quizizz. Open-ended responses were analyzed qualitatively to identify patterns, themes, and subjective insights regarding students' perceptions of Quizizz. The mixed-methods approach ensured a well-rounded evaluation of the impact of Quizizz on vocabulary acquisition, integrating numerical data with qualitative feedback for deeper analysis and interpretation.

4. Results



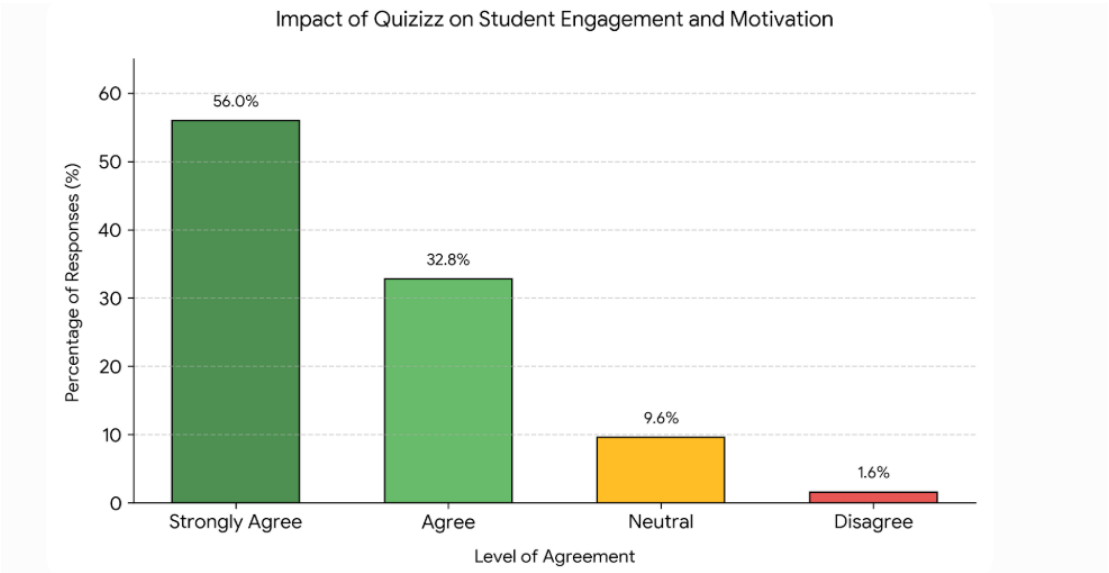
4.1 Overview of Findings

An overview of the respondents' demographics, including gender distribution and educational background, is given in this section. Knowing these demographics guarantees a variety of viewpoints when evaluating Quizizz's efficacy and aids in placing the results in context.

4.2 Effectiveness of Quizizz in Vocabulary Learning

Figure 1

Student Ratings of Quizizz Effectiveness in Vocabulary Acquisition

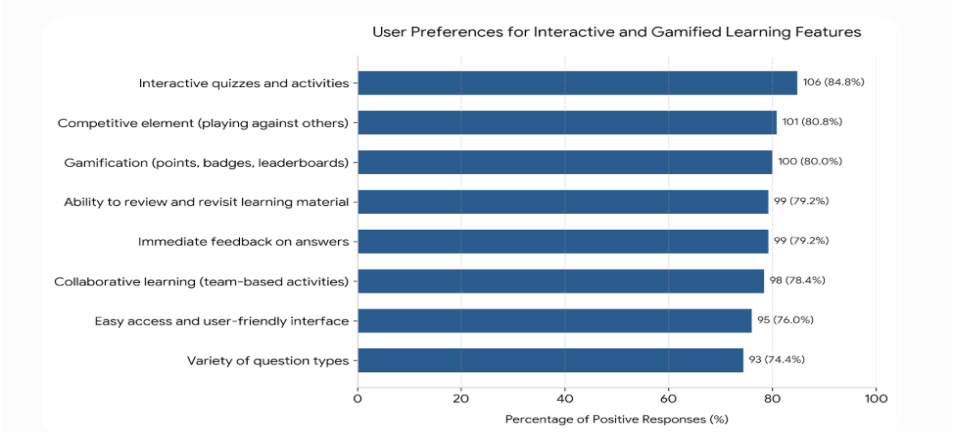


More than half of the participants gave the platform the highest possible rating of ten, while about a quarter of the group rated it slightly lower at nine or eight. A small percentage of students viewed its effectiveness as moderate, scoring it at a seven or six, and roughly one in twenty students gave it a neutral rating of five. On the other hand, dissatisfaction was remarkably low, with fewer than one percent of students assigning a rating of four, three, or two. Overall, these strongly positive reactions highlight that Quizizz successfully supports and enhances vocabulary acquisition for the clear majority of learners.

4.3 Engagement and Enjoyment

Figure 2

Impact of Quizizz on Student Engagement and Motivation

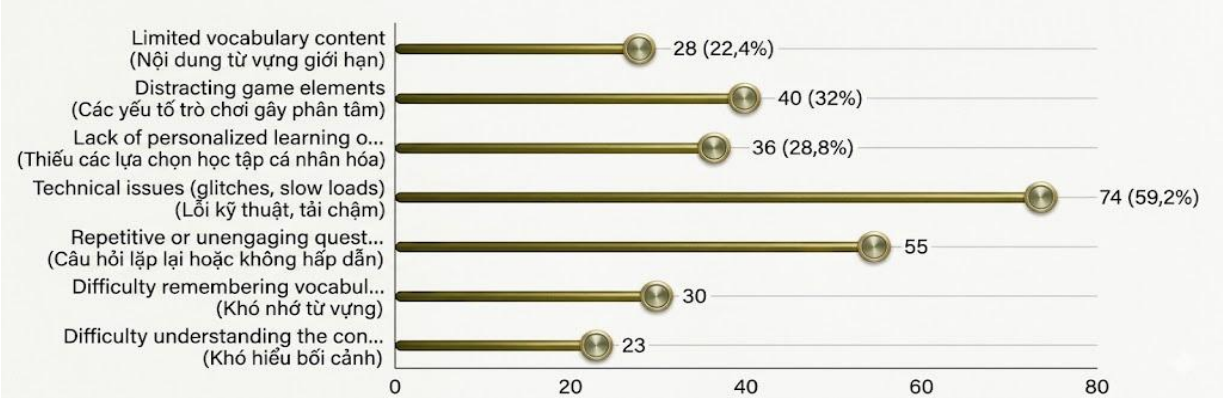


According to the findings, Quizizz greatly increased engagement. There was an 88.8% positive response rate, with 56% of students strongly agreeing and 32.8% agreeing that Quizizz made studying vocabulary more interesting and fun. In the meantime, a small portion disagreed, and 9.6% stayed neutral. This demonstrates how the platform's gamified and interactive features are essential for boosting motivation and making vocabulary learning more pleasurable.

4.4 Features that Enhance Vocabulary Learning

Figure 3

User Preferences for Interactive and Gamified Learning Features



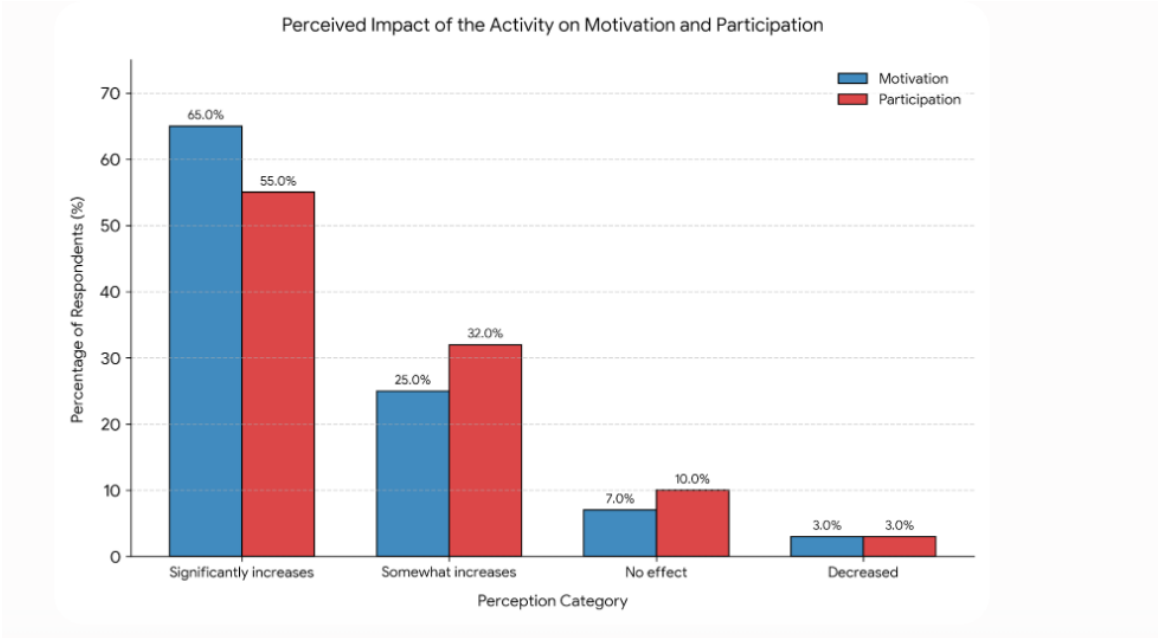
The horizontal bar chart, titled "User Preferences for Interactive and Gamified Learning Features," presents data on what users find most valuable in a modern learning environment, measured by both total count and percentage of positive responses. Out of the surveyed features, "Interactive quizzes and activities" ranks as the most preferred element, securing the highest approval at 106 responses (84.8%). Strong engagement is also seen in competitive and reward-based features, with "Competitive element (playing against others)" closely following at 101 responses (80.8%) and "Gamification (points, badges, leaderboards)" at 100 responses (80.0%). Review and feedback mechanisms also show high, identical utility among learners; both "Ability to review and revisit learning material" and "Immediate feedback on answers" tied at 99 responses (79.2%), while "Collaborative learning (team-based activities)" sits just a

fraction lower at 98 responses (78.4%). Rounding out the bottom of the preferences are "Easy access and user-friendly interface" with 95 responses (76.0%) and "Variety of question types" with 93 responses (74.4%). Overall, the chart demonstrates a consistently strong user demand for all listed interactive tools, with even the lowest-ranked feature enjoying an overwhelming popularity rate well above 70%.

4.5 Challenges in Using Quizizz

Figure 4

Challenges in Using Quizizz



The horizontal bar chart details various challenges and drawbacks encountered by users, detailing both the frequency and percentage of responses for each category. "Technical issues (glitches, slow loads)" stands out as the most prominent problem by a significant margin, reported by 74 respondents (59.2%). This is followed by concerns regarding content and gameplay design, where "Repetitive or unengaging questions" affected 55 users, and "Distracting game elements" were cited by 40 participants (32%). In terms of structural limitations, a "Lack of personalized learning options" was flagged by 36 respondents (28.8%), while "Limited vocabulary content" was noted by 28 users (22.4%). Finally, user-specific learning difficulties were less frequent but still present: 30 participants reported "Difficulty remembering vocabulary", and 23 users noted "Difficulty understanding the context" (18.4%). Collectively, the data indicate that software reliability and content engagement are the primary hurdles users face, while individual comprehension difficulties remain minor pain points by comparison.

4.6 Respondents' Perceptions of How the Activity Affects Their Motivation and Participation.

Figure 5

Perceived Impact of the Activity on Motivation and Participation

The chart illustrates respondents' perceptions of how the activity affects their motivation and participation. A large majority of participants reported that the activity significantly increases both their motivation and participation, with the highest percentages shown in the blue bars. Additionally, a considerable number of respondents indicated that the activity somewhat increases these aspects, as represented by the red bars. Only a small proportion believed that the activity had no effect, while very few respondents felt it decreased their motivation or participation. Overall, the findings suggest that the activity has a strongly positive impact on both motivation and participation.

5. Conclusion and discussion

5.1 Research Question Revisited

This study addressed the main research question by evaluating the extent to which Quizizz supports vocabulary learning among freshmen EFL students at HUFLIT. It also examined how Quizizz affects students' motivation and participation, which features students find most useful, and what challenges they encounter when using the platform for vocabulary learning.

5.2 Findings

The findings show that Quizizz's interactive and gamified features greatly improve student engagement and vocabulary retention. The study shows that using Quizizz increases student motivation, with many participants expressing a stronger desire to acquire language. The site also offers instant feedback, which promotes active recall and self-evaluation. However, some students encountered challenges such as repetitive question formats and limited opportunities for personalized learning. Despite these drawbacks, the findings confirm that Quizizz serves as an effective tool for vocabulary acquisition.

5.3 Explanation of Findings

The findings are consistent with earlier research highlighting the importance of gamification in language acquisition. Quizizz's competitive features, which boost motivation and strengthen vocabulary recall through repeated exposure, are responsible for its engagement-driven character. Additionally, by enabling students to track their development

and correct errors instantly, the quick feedback system promotes metacognitive techniques. However, some challenges, such as technical issues and repetitive content, may hinder the learning experience. These limitations suggest that while Quizizz is beneficial, its effectiveness can be optimized by incorporating more diverse question formats and adaptive learning features.

5.4 Limitations

The generalizability of the results is limited by the sample size, as the study only included freshmen EFL students at HUFLIT. Additionally, external factors such as students' prior experience with gamified learning and individual learning preferences might have influenced the findings. The study also did not account for long-term vocabulary retention beyond the immediate testing period. Future research should consider a broader sample size and a longitudinal approach to assess the sustained impact of Quizizz on vocabulary development.

5.5 Discussion

5.5.1 Implications

The results highlight the importance of using technology-driven learning resources in language instruction. Students' favorable reactions to Quizizz demonstrate how gamified platforms can improve learning results and engagement. Additionally, the study contends that interactive learning promotes self-directed learning habits and autonomy, both of which are critical for long-term language acquisition. To get the most out of Quizizz, teachers need to incorporate extra activities like group discussions and writing assignments to guarantee greater vocabulary understanding and real-world applications.

5.5.2 Recommendations

To optimize the effectiveness of Quizizz in vocabulary learning, educators should integrate it into formal instruction by aligning quizzes with course objectives. Enhancing Quizizz with multimedia elements such as images, audio pronunciations, and contextual examples can improve vocabulary retention and pronunciation accuracy. Diversifying question formats to include fill-in-the-blank, sentence construction, and open-ended responses would encourage critical thinking and deeper understanding. Additionally, incorporating personalized learning paths within Quizizz can cater to individual student needs, allowing for targeted vocabulary reinforcement. Finally, conducting follow-up assessments to measure vocabulary retention over time would provide valuable insights into the platform's long-term impact. By implementing these recommendations, Quizizz can become a more dynamic and effective tool for vocabulary learning, equipping students with essential linguistic skills for academic and professional success.

#59 Self- Reflection in Using GenAI for Learning: Perceptions of English-Majored Students at Binh Duong University- Ca Mau Campus

Liet Thoai Phuong Lan [1]

Abstract

Generative AI (GenAI) has revolutionised higher education, especially in English Language Studies. However, GenAI is most effective when it supports students in developing their own thinking. Therefore, this study examines the perceptions and self-reflection practices of English-major students regarding the use of GenAI in their academic paths. There were four keys: academic problem-solving, creative expression, communication, and decision-making, which were used to structure the self-reflection checklist. The research investigates how students balance the use of GenAI assistance with independent thinking across these key areas. The author employed a mixed-methods approach, using questionnaires for quantitative data collection and reflective journals and semi-structured interviews for qualitative data collection. Data were collected from 50 English major students at Binh Duong University - Ca Mau Campus. The results indicate that GenAI is widely used for drafting and refining ideas, but there is a clear need to develop strategic autonomy to avoid creative stagnation and over-dependence. Moreover, it highlights the importance of self-reflection as a pedagogical tool to promote ethical and effective AI integration in English Language Studies.

***Keywords*:** GenAI, self-reflection, English majors, learner autonomy, academic integrity

1. Introduction

Today, Artificial Intelligence (AI) has become useful in higher education. Generative Artificial Intelligence (GenAI) tools such as ChatGPT, Gemini, and Claude are increasingly used in educational settings, raising questions about their impact on student learning (Xiaodong Chen et al., 2026). Additionally, Kasneci et al. (2023) show that tools like ChatGPT can assist with language production, provide immediate feedback, and encourage learner independence. Teaching and learning have changed significantly with the adoption of GenAI. Nina Rizun et al. (2026) describe that ChatGPT and similar platforms are often used for idea generation, writing support, and language improvement in English Language Studies. Owing to these technological advantages, students are relying more on AI, which could hinder the development of critical thinking skills (Sofie Otto et al., 2025; Nina Rizun et al., 2026). These researchers warn that GenAI might create a false sense of ability, where students produce decent work without truly understanding the underlying processes. This trend raises important questions about student engagement and responsibility in AI-supported learning environments. To address these concerns, self-reflection has become an essential tool for meaningful learning. Instead of viewing GenAI as a substitute for critical thinking, self-reflection encourages students to evaluate when, why, and how they use AI tools. Therefore, this study contributes to the literature in three ways. Initially, it examines self-reflection as a mediating mechanism that shapes whether GenAI promotes learner autonomy or fosters dependency. In addition, it introduces a structured self-reflection framework that captures students' behaviours across four domains: academic problem-solving, creative expression, communication, and decision-making. More critically, it provides evidence from English-

[1] *Master of English Linguistics, Faculty of Foreign Languages, Binh Duong University-Ca Mau campus, Ca Mau City, Vietnam; Email: ltplan.cm@bdu.edu.vn*

major students in Binh Duong University – Ca Mau campus, which remains underrepresented in current AI-in-education research. By focusing on reflective engagement rather than merely frequency of AI use, the study offers a more nuanced understanding of sustainable and ethical AI-supported learning.

2. Literature Review

2.1. Self-Reflection and Learner Autonomy

Self-reflection is essential to metacognition and plays a crucial role in encouraging learner independence in higher education. Research shows that self-regulated learning involves continuous processes of planning, monitoring, and reflecting, enabling students to oversee their cognitive and behavioural actions (Zimmerman, 2000; Zimmerman, 2002; Panadero, 2017). Reflection helps students assess their performance and adjust their strategies, thereby enhancing learning effectiveness (Schön, 1983; Boud, Keogh & Walker, 1985). For example, structured reflection boosts students' motivation, self-confidence, and performance. These findings suggest that self-reflection is vital for meaningful learning, especially when learners encounter complex cognitive tasks.

2.2. Generative AI in Language Learning: Integrating

Generative Artificial Intelligence (GenAI) in education has created new opportunities for personalised learning. Students receive immediate feedback, brainstorm ideas, and get help with writing tasks, making these tools especially useful in English Language Studies through AI-based language models. Kasneci et al. (2023) argue that AI tools can support tailored learning paths and boost student engagement. Similarly, Zawacki-Richter et al. (2019) offer a comprehensive review showing that, when used correctly, artificial intelligence can improve teaching and learning. However, concerns about over-reliance on AI tools have also emerged. Debby R. E. Cotton et al. (2024) note that students may rely on AI to complete tasks without fully understanding the content, leading to superficial learning. This issue is especially important because writing is both a mental and creative process in language learning. Relying too much on GenAI could prevent the development of authentic voice, critical thinking, and language skills.

2.3. Self-Reflection in the Use of GenAI

The effectiveness of GenAI in education depends not only on access to technology but also on how learners engage with it. Self-reflection is essential in ensuring that AI tools serve as cognitive support rather than replacements for thinking. Ling Wei (2023) provides valuable insights for educators and researchers interested in incorporating AI-powered platforms into language classes. The findings support the idea that AI-enhanced language instruction can transform learning and highlight the positive influence of AI-driven educational tools. Similarly, the authors (2023) emphasise the importance of AI literacy, including the ability to critically evaluate AI outputs and recognise their limitations. In this context, structured reflection tools—such as self-reflection checklists—can be effective teaching strategies. These tools assist students in assessing their behaviours, identifying over-reliance, and developing more strategic approaches to AI use. Through detailed thematic analysis, this study identified both the advantages and disadvantages of AI-driven language education, highlighting AI's role in fostering self-regulated learning while addressing challenges such as technological dependence and equitable access.

2.4. Conceptual Framework

Building on the existing literature on Self-Regulated Learning, this study introduces a conceptual framework to analyse how students interact with GenAI while learning English. In this framework, GenAI use is viewed as a double-edged sword that can either support or hinder learning depending on how it is mediated through self-reflection. While GenAI offers benefits like idea generation, language correction, and feedback, unregulated use may lead to passive learning and over-reliance. Additionally, self-reflection plays a crucial role in influencing the effectiveness of GenAI use. Through reflective practices, learners' interactions with AI tools adjust their learning strategies and take ownership of their cognitive processes. Without proper training, these activities align with the self-reflection stage of the Self-Regulated Learning model, where learners evaluate outcomes and implement necessary changes. Specifically, learner autonomy is defined as the main outcome variable, representing students' ability to think independently, maintain their unique voice, and take responsibility for their learning. At the same time, the study introduces the concept of creative dependency as a negative outcome, describing a situation where students struggle to generate ideas or complete tasks without AI assistance.

In summary, the proposed model indicates that GenAI use influences both learner autonomy and creative dependence, but these effects are strongly affected by the level of self-reflection. High self-reflection leads to a strategic and effective use of GenAI, whereas low self-reflection increases the likelihood of dependence on GenAI.

2.5. Research Gap

Despite the rapid growth of research on Generative Artificial Intelligence (GenAI) in education, several important gaps remain unaddressed, particularly in English Language Studies. To begin with, most studies focus on the benefits and risks of GenAI, such as increased productivity, personalised feedback, and concerns about academic integrity, without thoroughly exploring the learning processes behind students' interactions with these tools. As a result, the existing literature often evaluates outcomes—such as performance and efficiency—rather than the cognitive and metacognitive mechanisms that support meaningful learning. Subsequently, although self-regulated learning and learner autonomy are well-studied in language education, their connection with GenAI use remains underexplored. Specifically, the role of self-reflection as a mediator between GenAI use and learning outcomes remains underexplored. Most previous studies treat AI use as a direct predictor of learning results, overlooking how reflective practices may enhance or limit their effectiveness. Of particular importance is the finding that there are no valid, practical tools to measure students' strategic versus dependent use of GenAI. Current research rarely operationalises learners' behaviours across multiple domains—such as academic problem-solving, creative expression, communication, and decision-making—making it difficult to identify subtle patterns, such as "creative dependency." Ultimately, data from non-Western contexts, especially Vietnam, is limited. Given the sociocultural and educational differences that influence technology use and learner autonomy, findings from Western settings cannot be easily generalised. Therefore, research focused specifically on local contexts that reflect teaching practices and student characteristics is needed. Lastly, unlike previous studies that primarily investigated attitudes toward GenAI or its impact on learning outcomes, the present study focuses on the reflective processes that shape students' interactions with AI. By conceptualising self-reflection as a mediating mechanism rather than a simple learner characteristic, this study offers a process-oriented perspective on AI-supported learning. To address these gaps, the current study uses a mixed-methods approach. It introduces a structured self-reflection framework to examine how English majors engage with GenAI across different

areas. By viewing self-reflection as a mediating factor, the study aims to improve understanding of how GenAI can support or hinder learner autonomy and sustainable learning practices.

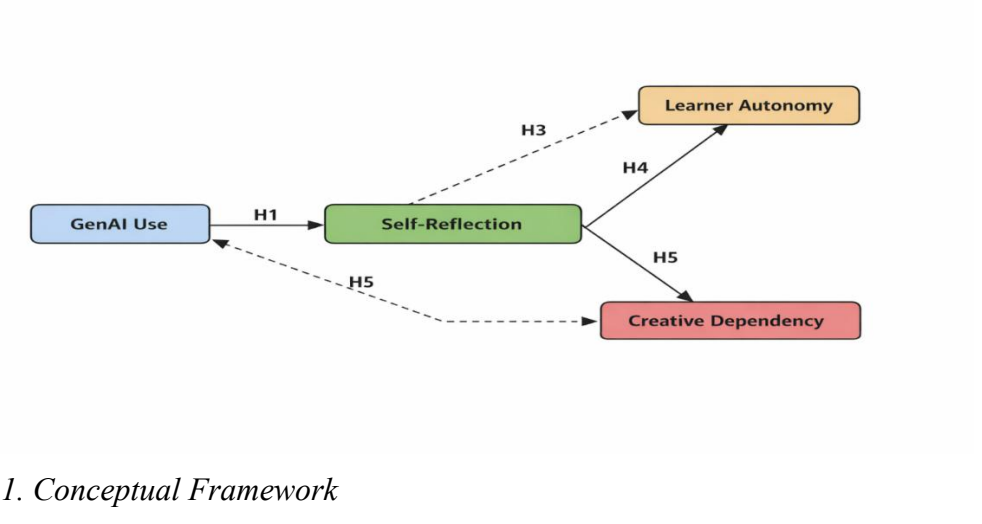

Image 2.1. Conceptual Framework

Note:

- *Solid lines (→) show the direct path of impact from behaviour (Gen AI use) → cognition (Self-reflection) →outcomes (Autonomy or dependency)*
- *Dashed lines (---->) illustrate the double-edged sword mechanism: self-reflection acts as a crucial mediator to achieve autonomy. At the same time, a lack of independent creativity can lead to an absolute reliance on AI.*

2.6. Research Hypotheses

According to the conceptual framework, the study suggests the following hypotheses:

H1: The use of GenAI is positively associated with students' perceived learning support among those majoring in English.

H2: Self-reflection is positively associated with learner autonomy.

H3: Self-reflection mediates the relationship between GenAI use and learner autonomy.

H4: Self-reflection has a negative relationship with creative reliance.

H5: Low levels of self-reflection are associated with increased use of GenAI in academic tasks.

3. Methodology

3.1. Research Design

This study used a mixed-methods research design, combining quantitative and qualitative approaches to gain a comprehensive understanding of students' GenAI use and reflection practices.

3.2. Participants

The participants included 50 English-major students at Binh Duong University – Ca Mau. Campus. These students had prior experience using GenAI tools in their academic work.

3.3. Instruments

(1) Questionnaire

A structured questionnaire was developed from a self-reflection checklist. It assessed students' behaviours across four areas: Academic problem-solving, Creative expression, communication, and Personal decision-making.

(2) Reflective Journals

Students were asked to record their experiences with GenAI, emphasising how they used the tool and how it affected their thinking.

(3) Semi-Structured Interviews

Interviews were carried out to gain a deeper understanding of students' perceptions and challenges.

3.4. Data Collection and Analysis

Quantitative data were analysed with descriptive statistics, while qualitative data were thematically coded. Combining both data types enabled triangulation and improved validity.

4. Results

4.1. Descriptive Statistics

Table 1

Descriptive Statistics of Key Variables

Variables	N	Mean	Std. Deviation
GenAI Use	50	4.12	0.68
Self-reflection	50	3.45	0.72
Learner Autonomy	50	3.58	0.65
Creative Dependency	50	3.21	0.74

Note. *Values based on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree).*

Table 1 presents the descriptive statistics of the key variables. The results show that students reported a high level of GenAI use (M = 4.12, SD = 0.68), indicating that AI tools are widely integrated into their academic routines. In contrast, self-reflection was at a moderate level (M = 3.45, SD = 0.72), suggesting that reflective engagement with GenAI is still developing. Additionally, learner autonomy was moderate (M = 3.58, SD = 0.65), while creative dependence was noticeable among students (M = 3.21, SD = 0.74). These findings point to a potential imbalance between technology use and independent thinking. Overall, the findings demonstrate that GenAI is extensively used by students, especially for idea generation, refining writing, and grammar checking. However, most students tend to use GenAI during the early stages of task completion, often before attempting independent thought.

4.2. Correlation Analysis

Table 2

Correlation Matrix among Variables

Variables	1	2	3	4
1. GenAI Use	1			
2. Self-reflection	.42**	1		
3. Learner Autonomy	.36*	.61**	1	

4. Creative Dependency	.48**	-.55**	-.40**	1

Note. *p < .05, **p < .01

The correlation matrix (Table 2) shows significant relationships among the variables. Self-reflection has a strong positive relationship with learner autonomy (r = .61, p < .01), supporting the idea that reflective practices boost independent learning. It is also negatively related to creative dependency (r = −.55, p < .01), indicating that students who reflect more are less likely to rely on GenAI. GenAI use is positively related to both learner autonomy (r = .36, p < .05) and creative dependency (r = .48, p < .01), highlighting its dual effect on learning outcomes.

4.3. Regression Analysis

To further investigate the relationships among variables, multiple regression analyses were performed.

An important observation emerging from the data is that GenAI use was a significant predictor of learner autonomy (β = .32, p < .05), supporting H1. However, its explanatory power was modest (R^2 = .13), indicating that other factors play a more significant role.

Table 3

Regression Analysis: GenAI Use Predicting Learner Autonomy

Variable	B	SE	Beta	t	Sig.
GenAI Use	.28	.11	.32	2.54	.014

R^2 = .13

The results also suggest that self-reflection demonstrated a strong positive effect on learner autonomy (β = .60, p < .001), accounting for a significant portion of the variance (R^2 = .37). This finding is consistent with self-regulated learning theory and supports H2.

Table 4.

Regression Analysis: Self-reflection Predicting Learner Autonomy

Variable	B	SE	Beta	t	Sig.
Self-reflection	.52	.09	.60	5.78	.000

R^2 = .37

To investigate the mediating role of self-reflection (H3), both GenAI use and self-reflection were included in the regression analysis. The results show that self-reflection remained a significant predictor (β = .55, p < .001). At the same time, the effect of GenAI use became non-significant (β = .14, p > .05). This suggests that self-reflection fully mediates the relationship between GenAI use and learner autonomy.

Table 5

Multiple Regression (Mediation Test)

Variable	B	Beta	Sig.
GenAI Use	.12	.14	.210
Self-reflection	.48	.55	.000

R^2 = .41

Finally, regression analysis revealed that self-reflection negatively predicts creative dependency ($\beta = -.52$, $p < .001$), supporting H4. It confirms that reflective learners are less likely to rely on GenAI. Additionally, the findings support H5, indicating that lower levels of self-reflection are associated with increased dependence on AI tools.

Table 6

Regression Analysis: Self-reflection Predicting Creative Dependency

Variable	B	Beta	Sig.
Self-reflection	-.46	-.52	.000

$R^2 = .27$

4.4. Relationship between Reflection and Autonomy

Overall, all proposed hypotheses were supported. The findings confirm that while GenAI use contributes to learning support, its effectiveness depends on students' reflective engagement. Self-reflection emerges as the key factor in enhancing learner autonomy and reducing creative dependency.

4.5. Qualitative findings

The author collected qualitative data from reflective journals and semi-structured interviews, which provided a much clearer sense of how students experienced GenAI. It also helped explain what the quantitative numbers really meant. Three themes emerged from the analysis.

Theme 1: GenAI as a Cognitive Scaffold.

For most of them, GenAI was a support tool. It helped them generate ideas and develop their language, but it did not replace their own thinking. Students often say they used it to get started on a task, consider different viewpoints, or clean up their writing. However, they also pointed out that we have to evaluate and adapt whatever the AI spits out critically. One participant put it like this: "*I usually ask ChatGPT for ideas when I start an essay, but I still need to reorganise and rewrite the content in my own way*" (Student 12). This finding suggests that students generally perceive GenAI as a cognitive scaffold that supports learning while still requiring active intellectual engagement.

Theme 2: Emerging Signs of Creative Dependency

Even students who saw GenAI's benefits had concerns about getting too dependent on it. Their journal entries showed a common worry. Frequent use of AI seemed to chip away at their confidence in generating original ideas on their own. The pattern was clear. They would turn to AI for suggestions before attempting the work themselves. One student was honest about it. "*Sometimes I cannot begin writing until I receive suggestions from AI*" (Student 27). That kind of comment points to something this study calls creative dependency. It describes a gradual shift where AI becomes the primary source of ideas and support. The dependency was probably not absolute for most students. Still, the findings hint at a real risk to independent thinking and to their creative confidence down the line.

Theme 3: Reflection as a Protective Mechanism

The qualitative findings also pointed to how self-reflection helped students manage their use of GenAI. People who took time to think about their interactions with AI seemed more aware of what these tools could and could not do. They tended to review AI suggestions more

carefully, compare them with their own thinking, and decide whether to use them. One student said, "*When I compare my first draft with AI suggestions, I can identify weaknesses in my thinking and improve my work*" (Student 35). So, self-reflection works like a safeguard. It keeps students from relying too heavily on AI by prompting them to reflect on their own thinking. Which means they retain control over their own learning. Moreover, for those like Student 35, that is what makes the difference.

5. Discussion

This study's results mostly back the conceptual framework the author laid out. Self-reflection matters a lot here. It mediates how GenAI use affects learning outcomes. First of all, the data confirmed H1, showing that GenAI use is positively associated with perceived learning support. Students said they often use GenAI to brainstorm ideas, polish their language, and finish assignments. Then, for H2, the results suggest that self-reflection and learner autonomy go hand in hand. Students who reflected more often tended to develop their own ideas and to evaluate the AI's output critically. They also kept their personal voice in their work. More importantly, the study found that the direct contribution of GenAI use became statistically insignificant once self-reflection was introduced into the model. So, this pattern supports H3 in suggesting that reflective engagement may be the mechanism through which learners transform AI-generated assistance into meaningful learning experiences. GenAI shifts from being a tool for efficiency into more of a cognitive partner, one that actually encourages deeper learning. Besides, the results also support H4. There is a clear negative relationship between self-reflection and creative dependence. Students who practised reflection relied less on GenAI and seemed more confident working through tasks independently. Students with low reflection levels, however, often struggled to generate ideas without AI. This action suggests they are gradually depending more on external support than on their own thinking. Finally, the findings support H5: Students who do not reflect much tend to lean more heavily on GenAI for academic tasks. The study calls this creative dependency. Regularly using AI makes independent thinking harder over time. These results confirm the model we proposed. What stands out is how GenAI's impact on learning is not straightforward. It depends heavily on the learner's reflective engagement. Self-reflection is not just a useful habit. It may be what decides whether AI helps a student or makes them more dependent. From a theoretical perspective, the study extends existing models of self-regulated learning by incorporating GenAI as a contextual factor and by emphasising the mediating role of reflection. From a teaching perspective, these findings suggest that educators should go beyond simply integrating AI tools into the classroom and focus on developing students' reflective skills. Without these efforts, widespread use of GenAI could unintentionally reduce learner autonomy and increase dependence. In conclusion, the discussion confirms that the effectiveness of GenAI in English depends on effective thinking, which supports the study's central argument: GenAI supports learning only when it promotes thinking, and reflection is essential for that.

6. Implications

The findings of this study provide significant implications for teaching, curriculum development, and future research in integrating Generative Artificial Intelligence (GenAI) into English Language Studies.

6.1. Pedagogical Implications

The study emphasises the crucial role of self-reflection in improving the effectiveness of GenAI use. Therefore, language teachers should not only promote the use of AI tools but also instruct students in using them thoughtfully. The teachers can achieve this by incorporating

reflective tasks into classroom activities. For example, teachers might ask students to explain how they used GenAI, evaluate its outputs, and compare AI-generated content with their own ideas. Additionally, teachers should assign tasks that require students to demonstrate independent thinking before engaging with GenAI. For instance, students could submit initial drafts or outlines before interacting with AI tools. These practices help prevent passive reliance and encourage deeper cognitive engagement. Furthermore, assessment methods should include reflective components. Instead of solely assessing final products, educators should evaluate the learning process, including students' decision-making and their use of AI. This approach supports the development of learner autonomy and maintains academic integrity.

6.2. Curriculum and Institutional Implications

At the curriculum level, the findings suggest a need to incorporate AI literacy and reflective learning into English language programs. Courses should include explicit instruction on how to critically evaluate AI-generated content, recognise its limitations, and use it responsibly. Institutions should also establish clear guidelines for the proper use of GenAI in academic work. Despite implementing restrictive policies that discourage AI use, universities should adopt a balanced approach that promotes responsible and strategic engagement. Additionally, professional development programs should be offered to help instructors effectively integrate GenAI and reflective practices into their teaching. Teachers may struggle to guide students in meaningful AI use without proper training.

6.3. Theoretical Implications

This study expands the existing literature by broadening the Self-Regulated Learning (SRL) framework to include AI-supported learning environments. The study offers a clearer understanding of how GenAI influences learning outcomes by positioning self-reflection as a mediating variable. Introducing "creative dependency" as a concept enriches the discussion of the unintended effects of AI use in education and offers a useful perspective for future research exploring the balance between technological support and cognitive independence.

6.4. Implications for Future Research

Future research should increase sample sizes and also include participants from diverse institutions and fields to enhance generalizability. Long-term studies are also needed to examine how students' reflective practices and their use of GenAI develop over time. Additionally, developing and validating measurement tools should be focused on assessing reflective AI use across various learning contexts. Experimental studies could also evaluate the effectiveness of specific teaching methods designed to promote self-reflection. In summary, this study highlights that successfully integrating GenAI into education depends on both access to technology and the development of learners' reflective and self-regulatory skills. By fostering these abilities, educators can ensure that GenAI serves as a resource for learning rather than a shortcut that undermines it.

7. Conclusion

This study highlights the importance of self-reflection for effective use of GenAI in English Language Studies. Although GenAI provides significant benefits, its educational value depends on how students interact with it. Besides, self-reflection helps learners remain independent, maintain academic integrity, and deepen their understanding. Therefore, it is essential to incorporate reflective practices in teaching and assessment to maximise GenAI's potential. Future research should involve larger samples and create validated frameworks for measuring reflective AI use across different educational settings.

TỰ PHẢN TƯ TRONG VIỆC SỬ DỤNG TRÍ TUỆ NHÂN TẠO TẠO SINH (GenAI) ĐỂ HỌC TẬP: NHẬN THỨC CỦA SINH VIÊN NGÀNH NGÔN NGỮ ANH TẠI TRƯỜNG ĐẠI HỌC BÌNH DƯƠNG – PHÂN HIỆU CÀ MAU

Liet Thoai Phuong Lan

TÓM TẮT - Trí tuệ nhân tạo tạo sinh (GenAI) đã mang lại những thay đổi căn bản trong giáo dục đại học, đặc biệt là trong lĩnh vực nghiên cứu ngôn ngữ Anh. Tuy nhiên, GenAI chỉ thực sự phát huy hiệu quả tối đa khi đóng vai trò hỗ trợ sinh viên phát triển tư duy độc lập. Do đó, nghiên cứu này tìm hiểu nhận thức và thực hành tự phản tư của sinh viên chuyên ngành tiếng Anh về việc sử dụng GenAI trong quá trình học tập. Thông qua bảng kiểm tự phản tư (self-reflection checklist) có cấu trúc, nghiên cứu khám phá cách sinh viên cân bằng giữa sự hỗ trợ của GenAI và tư duy độc lập trên bốn lĩnh vực chính: giải quyết vấn đề học thuật, biểu đạt sự sáng tạo, giao tiếp và ra quyết định. Nghiên cứu sử dụng phương pháp hỗn hợp (mixed methods), kết hợp bảng hỏi để thu thập dữ liệu định lượng, cùng với nhật ký phản tư và phỏng vấn bán cấu trúc. Đối tượng khảo sát gồm 50 sinh viên chuyên ngành Ngôn ngữ Anh tại Trường Đại học Bình Dương – Phân hiệu Cà Mau. Kết quả sơ bộ cho thấy, dù GenAI được sử dụng rộng rãi để soạn thảo và trau chuốt ý tưởng, việc phát triển tính tự chủ chiến lược là vô cùng cấp thiết nhằm tránh tình trạng rỗng tuếch về sáng tạo và sự lệ thuộc quá mức. Nghiên cứu nhấn mạnh vai trò của tự phản tư như một công cụ sư phạm nhằm thúc đẩy việc tích hợp AI một cách đạo đức và hiệu quả trong đào tạo ngôn ngữ Anh.

Từ khóa: GenAI, tự phản tư, chuyên ngành tiếng Anh, tính tự chủ của người học, liêm chính học thuật

MA. Liet, T. P. Lan (Liet Thoai Phuong Lan) earned two master's degrees: an M.A. in English Language from Ho Chi Minh City University of Technology (HUTECH) and an M.A. in Measurement and Evaluation in Education from Vietnam National University, Hanoi. She obtained her bachelor's degree in English from Can Tho University. Since 2000, she has been a teacher at Ca Mau Community College. She currently works as an English language lecturer at Binh Duong University – Ca Mau Campus, Vietnam. With over 25 years of teaching experience in higher education, her academic interests include language teaching methodology, learner autonomy, educational assessment, and the use of emerging technologies, especially Generative AI, in English language learning.

Appendices

STUDENT SELF-REFLECTION ON STRATEGIC GENAI USE

Research Topic: Self-Reflection in Using GenAI for Learning: Perceptions of English-Majored Students at Binh Duong University - Ca Mau Campus

PART 1: GENERAL INFORMATION

Full Name (Optional): _____

Academic Year/Class: _____

Frequency of GenAI use (ChatGPT, Claude, Gemini, etc.):

[ ] Daily [ ] Weekly [ ] Rarely / Never

PART 2: SELF-REFLECTION SURVEY

Please check the boxes that accurately describe your current habits when using GenAI.

Section A: Academic Thinking and Problem-Solving

Strategic Use (Positive Habits):

1. [ ] I attempt problems independently first, then use GenAI to check my approach.
2. [ ] I can explain my work clearly without needing to reference GenAI.
3. [ ] I can complete similar tasks even when GenAI is unavailable.
4. [ ] I immediately turn to GenAI when encountering challenges without trying first.

Section B: Creative Work and Expression

Strategic Use (Positive Habits):

5. [ ] I generate initial ideas independently, then use GenAI to build and explore them.
6. [ ] I maintain a recognisable personal style across all my English assignments.
7. [ ] I feel "creatively empty" without GenAI to start my writing process.
8. [ ] My work has started looking generic or obviously AI-generated.

Section C: Communication and Social Skills

Strategic Use (Positive Habits):

9. [ ] I draft important messages myself, then might use GenAI to refine them.
10. [ ] I can handle unexpected social situations without needing GenAI preparation.
11. [ ] When I need emotional support, I turn to trusted people rather than GenAI.

Section D: Personal Decision-Making

12. [ ] I form my own opinions first, then seek GenAI’s perspective as one input.
13. [ ] My decisions feel authentically mine.
14. [ ] I struggle to make decisions when GenAI is not available.

#61 Exploring EFL Freshmen's Motivation for Choosing a Career in Teaching English: A Case Study at A Public University in Ho Chi Minh City

Son Le Anh, Tai Phan Tan , Thanh Lam Thanh, Tam Huynh Ngoc, Vy Nguyen Pham Tuong, Hieu Duong Thi Le & Ha Nguyen Thi

Abstract

English language teaching is growing rapidly in Vietnam. Therefore, understanding why students choose this career is very important to help universities support and develop future teachers. This study aims to explore the career motivations of freshmen in the English Pedagogy major at a public university in Ho Chi Minh City. It also examines whether gender and previous teaching experience create any differences in their motivations. The study used a quantitative method. Data was collected from 101 first-year students using a 25-item questionnaire based on the FIT-Choice framework. The collected data was then analyzed using SPSS software with descriptive statistics, Pearson correlations, and t-tests. The findings showed that students reported high levels of motivation across all FIT-Choice constructs. Task Demand and Task Return and Socialization Influences received the highest mean scores, while altruistic and intrinsic motivations also emerged as prominent reasons for choosing teaching. Extrinsic motivation, particularly fallback careers, received the lowest ratings. In conclusion, first-year EFL students proactively choose the teaching profession because of their true passion for English and a desire to contribute to society, rather than seeing it as a secondary option. These findings provide helpful evidence for universities to build better strategies to nurture students' passion for teaching.

***Keywords*:** career motivation, FIT-Choice framework, EFL freshmen, pre-service teachers, English Pedagogy

1. Introduction

1.1. Background to the Study

English has become an essential medium for global communication, education, and professional development, leading to an increasing demand for qualified English language teachers in many countries, including Vietnam. As educational systems continue to face challenges related to teacher recruitment and retention, understanding why individuals choose teaching as a career has become an important research concern (Müller et al., 2009; Watt & Richardson, 2007). Career motivation is particularly significant because it influences not only

entry into the profession but also professional commitment, persistence, and long-term career satisfaction (Richardson & Watt, 2006; Watt & Richardson, 2007).

1.2 Statement of the Problem

To investigate motivations for choosing teaching, researchers have widely adopted the Factors Influencing Teaching Choice (FIT-Choice) framework developed by Watt and Richardson (2007). Drawing upon Expectancy-Value Theory (Eccles et al., 1983), the framework explains how individuals' career decisions are shaped by intrinsic interest, social utility values, personal utility values, perceived ability, social influences, and perceptions of the teaching profession. Across diverse educational contexts, studies have consistently found that intrinsic and altruistic motivations are among the strongest reasons for entering the teaching profession, whereas extrinsic considerations such as salary, social status, or fallback

career opportunities tend to be less influential (Asriani et al., 2022; Lee et al., 2019; Pavin Ivanec, 2023; Saito, 2024).

1.3 Research Gap

Within the Vietnamese context, previous research has reported similar patterns, highlighting the importance of personal interest in teaching and the desire to contribute to society (Tran & Cao, 2020). However, recent policy initiatives, particularly Decree No. 116/2020/NĐ-CP, which provides financial support for teacher education students, have introduced additional contextual factors that may shape students' career decisions (Tran et al., 2025). These developments suggest the need for continued investigation of teacher motivation within contemporary Vietnamese educational settings.

1.4 Research Objectives and Research Questions

To fill these gaps, this study aims to explore the career motivations of first-year English pedagogy students at a public university in Ho Chi Minh City. By surveying freshmen without formal teaching experience, this research provides a complete and authentic view of why they chose this major. Specifically, the study seeks to answer the following questions: (1) What are the primary FIT-Choice motivational factors underlying the career choices of first-year English Pedagogy students? and (2) To what extent do gender and prior informal teaching experience differentiate their motivational profiles?

1.5 Significance of the Study

Theoretically, this study extends the application of the FIT-Choice framework to first-year EFL teacher education students, a relatively underexplored population in Vietnam. By focusing on freshmen, the study provides insights into career motivations at an early stage of teacher development before extensive pedagogical training and professional socialization occur. Additionally, the study examines motivational differences across gender and prior teaching experience groups, contributing to a more nuanced understanding of teacher motivation within the Vietnamese context. Practically, the findings offer useful implications for teacher education institutions and policymakers. Understanding the factors that motivate students to pursue English language teaching can support the development of recruitment strategies, orientation programs, and student support initiatives aimed at sustaining motivation and strengthening commitment to the teaching profession.

1.6 Scope and Delimitations

This study focuses on English language teaching first-year students of the Faculty of Foreign Languages at a public university in Ho Chi Minh City, Vietnam. Moreover, data were collected from participants at a single point in time to examine their career motivations. This research intentionally focuses only on first-year English Pedagogy students because they have had limited exposure to pedagogical coursework and teaching practicum, allowing the research to capture their initial career motivations before they are substantially influenced by teacher education. In addition, the study is confined to one public university and adopts a quantitative survey design. Consequently, qualitative perspectives and changes in motivation over time are beyond the scope of the present study.

2. Literature Review

2.1 Definitions of motivation

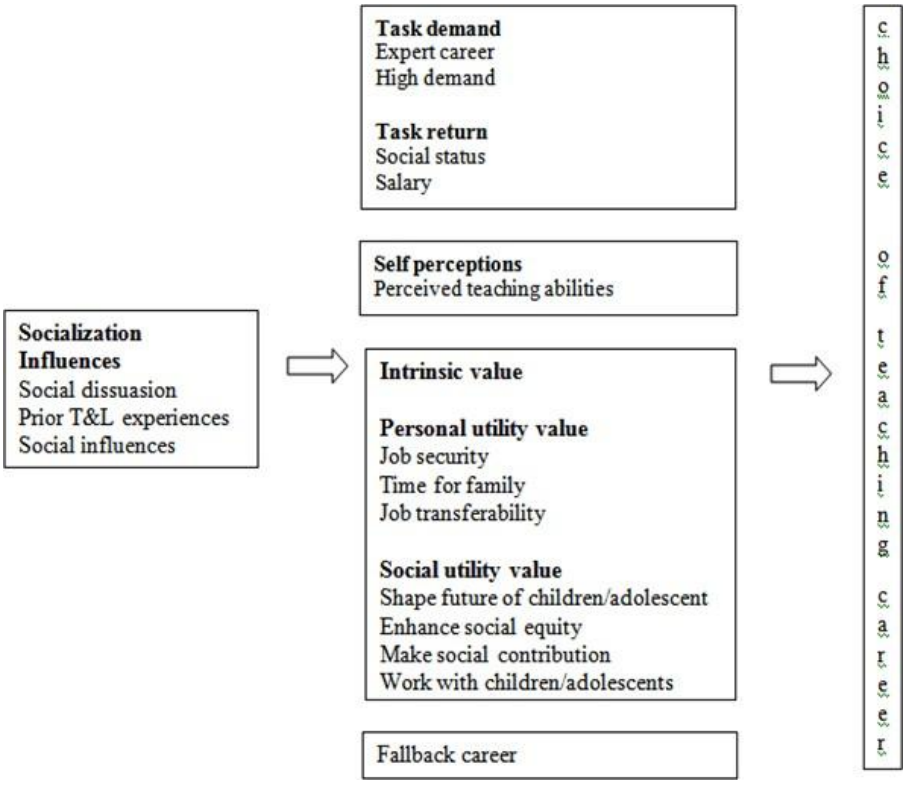
Motivation is a multifaceted psychological construct that serves as the internal engine for human behavior, initiating and guiding goal-oriented actions through the interplay of

biological, emotional, and cognitive forces (Guay et al., 2010). In its broadest sense, it is defined as the process whereby activity is instigated and sustained (Schunk et al., 2010), varying not only in level but also in orientation, the underlying "why" that moves an individual to act (Deci & Ryan, 2000). In teacher education, motivation is key to attracting and keeping teachers. It decides who joins the profession, how they study during training, and their long-term commitment to teaching (Müller et al., 2009). For first-year students, these early drivers show their "pure" career goals before they face the real challenges of teaching practice (Dewi & Fajri, 2023; Sinclair et al., 2006). Therefore, understanding why students choose this career helps us see how they build their professional identity and stay determined in a university environment.

2.2. Types of motivation

Motivation has been categorized into three main sources: extrinsic, intrinsic and altruistic. Deci & Ryan (2000) demonstrated that motivation includes two kinds: intrinsic and extrinsic. To be more specific, intrinsic motivation refers to doing something because of innate interest or enjoyment, which in the context of teaching may include feelings of enjoyment and satisfaction (Wang & Wang, 2022). On the other hand, extrinsic motivation is related to doing something because of a possible external result (Deci & Ryan, 2000) such as salary (Balyer & Özcan, 2014; Cheung & Yuen, 2016) or the status of the profession (Han & Yin, 2016). Specifically, altruistic motivation refers to the desire to help others and contribute to society (Virtanen et al., 2025). Moreover, Brookhart and Freeman (1992) synthesized research on motivation to conclude that intrinsic, extrinsic and altruistic are the main factors that motivate people to do something, especially choosing a teaching profession, such as making a difference in society and shaping the future of others (Başöz, 2021; Brandmo & Nesje, 2017; Richardson & Watt, 2006). The FIT-Choice framework (Watt & Richardson, 2007) systematically conceptualizes these dimensions, offering a comprehensive model for vocational choice in teaching.

2.3. FIT-Choice Framework



The FIT-Choice model, created by Watt and Richardson (2007), is a popular tool for studying teacher motivation in many countries, including South Korea (Jeong, 2016; Lee et al., 2019), Finland (Goller et al., 2019), Indonesia (Asriani et al., 2022; Sari, 2023), and more recently in the Vietnamese EFL context (Tran & Cao, 2020). Based on the Expectancy-Value Theory, this model suggests that career choices depend on two main things: what a person believes they can do and how much they value the job. Many factors shape this choice, such as past learning experiences and advice from family or friends. A key part of the model is perceived ability, where students judge their own English and teaching skills before joining the profession.

The model also breaks down values into three specific groups. First is intrinsic value, which is the love for the subject or teaching itself. Second is personal utility value, involving job security, time for family and job transferability. Third is social utility value, which is the desire to help children and society. These values are taken into consideration by task perceptions, such as the balance between hard work and rewards like salary or social status.

Finally, the model looks at fallback career factors to see if someone chose teaching just because they failed to get into their favorite major.

Figure 2.3

The Fit-Choice model (Watt & Richardson, 2007, p.176)

Overall, the FIT-Choice framework helps us understand how personal goals, skills, and the desire to help others come together to form a student's professional identity. This provides a strong foundation to explain why they chose English teaching and how committed they will be in the future.

2.4. Previous studies

Global research from Western (Spain, Scotland, Norway, Ireland, Sweden) to Eastern cultures (Indonesia, Korea, Japan), even mixed cultures such as Turkey consistently identifies altruistic and intrinsic factors as the primary motivators for choosing a teaching career. Conversely, extrinsic motivation, particularly fallback careers, salary, and social status, are frequently reported as the lowest-rated motivations (Asriani et al., 2022; Başöz, 2021; Hennessy & Lynch, 2017; Kilinç et al., 2012; Lee et al., 2019; Nesje et al., 2018; Pavin Ivanec, 2023; Saito, 2024; Wang et al., 2022).

In the Vietnamese context, quantitative studies reinforce the dominance of altruistic and intrinsic motivations, often derived from students' prior learning experiences. (Tran & Cao, 2020). However, extrinsic factors have gained prominence, specifically the impact of Decree No. 116/2020/NĐ-CP, which provides significant financial support to teacher candidates (Tran et al., 2025).

2.5. Gap

Although the FIT-Choice framework has been extensively applied in studies of teacher motivation, several gaps remain in the current literature. First, many previous studies have focused on pre-service teachers from mixed year levels or students who have already completed substantial pedagogical coursework and teaching practicum experiences (Tran & Cao, 2020). Such experiences may influence students' professional beliefs and career motivations, making

it difficult to distinguish between initial motivations and motivations that develop during teacher education programs (Sinclair et al., 2006).

Second, relatively limited attention has been given to first-year English Pedagogy students in Vietnam. As freshmen are at the beginning of their academic journey and have had limited exposure to formal teacher training, investigating this population may provide a clearer understanding of the motivations that initially attract students to the teaching profession. Examining these early-stage motivations is important because they may serve as a foundation for later professional identity development and career commitment.

Third, while previous Vietnamese studies have primarily focused on identifying dominant motivational factors, less attention has been paid to potential variations in motivation associated with demographic characteristics such as gender and prior teaching experience. Exploring these differences may contribute to a more nuanced understanding of teacher motivation and provide insights into how different groups of students perceive the teaching profession at the beginning of their university studies.

2.6. Theoretical implications

Using the FIT-Choice framework to study first-year English pedagogy students brings several useful theoretical benefits. First, this study helps expand the FIT-Choice model by testing it on a very specific group: freshmen in a Vietnamese English-teaching context. Because these students have not started real teaching practice yet, looking at their answers helps us understand their original reasons for choosing this job. This adds a new time-based perspective to the current theory, showing what motivates students before they are changed by university training. Second, by looking at how gender and previous experience affect students' choices, the study adds more details to the theory about how personal backgrounds shape a student's values, such as wanting to help society or looking for job security. Finally, this research helps improve the theory on teacher identity. It explains how a student's early belief in their own skills and their desire to help others act as the starting points for their future love and commitment to the teaching career.

3. Methodology

3.1. Research design

This study adopted a quantitative cross-sectional survey design to investigate the career motivations of first-year English pedagogy students at a public university in Ho Chi Minh City, Vietnam. According to Creswell and Creswell (2018), A cross-sectional survey design was considered appropriate because data were collected from participants at a single point in time to examine their career motivations without any intervention or manipulation of variables (Creswell & Creswell, 2018). Furthermore, the research was conducted at the Faculty of Foreign Languages of a public university located in Ho Chi Minh City, Vietnam. With a long history in teacher education, this research location provides an ideal and suitable context to explore what drives freshmen to become English teachers.

3.2. Participants

The participants were carefully selected based on two limiting conditions: they must be first-year students, and they must currently study in the English Pedagogy major. At first, the survey reached 103 students. However, after data cleaning, two invalid responses were removed. Therefore, the final sample consisted of 101 participants. In terms of gender, female students accounted for the majority with 68 participants (67.3%), while male students made up 33 participants (32.7%). Regarding prior teaching experience, 58 students (57.4%) reported

that they had previous teaching experience (such as tutoring), whereas 43 students (42.6%) had no teaching experience.

3.3. Sampling technique

The participants were selected using convenience sampling from the EFL pedagogy classes at a university in Ho Chi Minh. A convenience sampling method was employed because all first-year English Pedagogy classes that were accessible during the data collection period were invited.

3.4. Instruments and Materials

A structured questionnaire was the main tool for collecting data. As noted by Brace (2004), questionnaires are highly effective for gathering a large amount of information about people's attitudes within a specific group. The questionnaire was administered via Google Forms and divided into two main sections:

Section 1: Demographic Information. This section collected basic information, including the students' gender and prior teaching experience.

Section 2: Career Motivations. This section comprised 25 items adapted from the Factors Influencing Teaching Choice (FIT-Choice) framework developed by Watt and Richardson (2007). Minor wording modifications were made to ensure suitability for the Vietnamese higher education context while maintaining the original meanings of the constructs. It measured six main constructs: Intrinsic Motivation (3 items), Altruistic/Social Utility Motivation (4 items), Extrinsic/Personal Utility Motivation (6 items), Perceived Ability (2 items), Task Demand and Task Return (6 items), and Socialization Influences (4 items). All items used a 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree).

Before the main survey, reliability of each construct was subsequently examined using Cronbach's alpha after data collection.

Table 3.4

Reliability statistics for the FIT-Choice constructs

Motivational Constructs	Number of Items	Cronbach's Alpha
Intrinsic Motivation	3	.715
Altruistic/Social Utility Motivation	4	.892
Extrinsic/Personal Utility Motivation	6	.782
Perceived Ability	2	.840
Task Demand and Task Return	6	.850
Socialization Influences	4	.751

3.5. Procedures

Data was collected through four sequential stages and was carried out step by step. First, the questionnaire was adapted from the FIT-Choice framework and modified to fit the Vietnamese context. After that, it was created as an online survey using Google Forms. Before the official collection, a pilot study was conducted in one day with 15 freshmen and 1 lecturer.

The purpose was to check if the questions were clear enough to distribute to the first-year English pedagogy students. Based on feedback from both the lecturer and the pilot participants, the questionnaire was revised and finalized. Next, the official questionnaire was distributed to the first-year English Pedagogy students via Google Forms. Before participating, all volunteers received clear explanations about the study's purpose and provided their consent. This official collection phase lasted for four days. Finally, after the survey had been closed, all responses were screened for completeness and consistency. Incomplete or invalid responses were removed from the dataset. The remaining data were coded and entered into SPSS version 26.0.

3.6. Variables

The study involved two main types of variables. The independent variables were the students' demographic characteristics, specifically their gender (male or female) and prior teaching experience (yes or no). Meanwhile, the dependent variables were the students' career motivations. These motivations were measured through their scores on the 25-item FIT-Choice questionnaire, which covered the six main motivation constructs.

3.7. Data analysis

SPSS software (version 26) was used to analyze the collected data. First, descriptive statistics, including means and standard deviations, were used to summarize the students' motivation levels. Next, a Pearson correlation test was applied to find the relationships between the six motivation factors. Finally, independent samples t-tests were conducted to compare the motivation scores between different groups (male vs. female and experienced vs. inexperienced). These statistical tools provided clear evidence to fully answer the research questions.

4. Results

4.1. Research question 1: What are the primary FIT-Choice motivational factors underlying the career choices of first-year English Pedagogy students?

4.1.1. Overall Picture of Career Motivational Factors

Table 4.1.1

Descriptive statistics of FIT-Choice motivational factors influencing career choice

Motivational Constructs	M	SD
Task Demand and Task Return	4.32	0.61
Socialization Influences	4.14	0.70
Altruistic/Social Utility Motivation	4.10	0.86
Intrinsic Motivation	3.98	0.77
Perceived Ability	3.78	0.85
Extrinsic/Personal Utility Motivation	3.60	0.83

Descriptive statistics indicate that first-year English Pedagogy students reported generally high levels of career motivation across the six FIT-Choice constructs. Among these, Task Demand and Task Return received the highest mean score (M = 4.32, SD = 0.61),

followed by Socialization Influences (M = 4.14, SD = 0.70) and Altruistic/Social Utility Motivation (M = 4.10, SD = 0.86). These findings suggest that participants generally recognized both the characteristics of the teaching profession and the influence of significant others when considering teaching as a career. In contrast, Extrinsic/Personal Utility Motivation received the lowest mean score (M = 3.60, SD = 0.83), although it remained above the midpoint of the scale. This indicates that external or personal utility considerations were less strongly endorsed than other motivational dimensions among the participants. Also, this overall pattern appears inconsistent with the common perception that students choose the teaching profession primarily for extrinsic rewards like the financial support policies from Decree No. 116/2020/ND-CP (Tran et al., 2025) or due to a lack of career orientation. Instead, they enter the field with a clear and realistic awareness of the difficulties and specific characteristics of the teaching profession.

4.1.2. Detailed Analysis of Motivational Constructs

Table 4.1.2

The descriptive statistics of all motivational items based on the FIT-Choice framework

Constructs and Items	M	SD
Task Demand and Task Return		
(E.1) Teaching English requires a high level of specialized knowledge.	4.56	0.73
(E.2) Teaching English requires a high level of pedagogical skills.	4.53	0.74
(E.4) Teaching English is a heavy workload/demanding profession.	4.41	0.80
(E.3) Teaching English requires hard work and high emotional demand.	4.32	0.75
(E.6) English teachers have a good salary/income.	4.21	0.80
(E.5) Teaching is a high-status profession in Vietnam.	3.91	0.98
Socialization Influences		
(F.3) My former teachers have inspired me to be a teacher.	4.28	0.90
(F.4) People around me thought I would make a good teacher.	4.20	0.92
(F.2) My family members influenced my decision to become a teacher.	4.13	0.95
(F.1) My friends influenced my decision to become a teacher.	3.95	0.95
Altruistic/Social Utility Motivation		
(B.2) I want to be a positive influencer on the future of students/pupils.	4.31	0.94
(B.1) I want to contribute to the development of society through teaching.	4.12	0.92
(B.4) Teaching English allows me to benefit the socially disadvantaged.	4.06	0.99
(B.3) I feel pleased because teaching allows me to work with children.	3.92	1.09
Intrinsic Motivation		
(A.1) I love the English language subject and want to work directly with it.	4.24	0.81
(A.2) I believe the teaching profession will bring me long-term enjoyment.	4.03	0.91
(A.3) I have always wanted to become a teacher.	3.68	1.15
Perceived Ability		
(D.1) I have good English language skills for teaching.	3.80	0.91
(D.2) I have good pedagogical skills.	3.76	0.92
Extrinsic & Personal Utility Motivation		
(C.1) Teaching English will be a secure job.	4.12	0.93
(C.6) I think teaching will allow me to work anywhere.	3.93	0.93
(C.3) The teaching profession offers me time for family.	3.80	1.07
(C.2) I do not worry about unemployment when teaching English.	3.65	1.21

Constructs and Items	M	SD
(C.4) I chose this major because of financial support policies (Decree 116).	3.54	1.35
(C.5) I chose this major as a fallback career (secondary option).	2.54	1.56

Table 4.1.2 provides a closer look at the specific survey items, showing some clear trends in why students choose this major. For Task Demand, students showed a very realistic understanding of the job's requirements. They gave very high scores to statements saying that teaching requires a "high level of specialized knowledge" (M = 4.56) and "pedagogical skills" (M = 4.53). These scores are much higher than their expectations for a "good salary" (M = 4.21). These findings indicate that participants generally agreed that teaching requires substantial professional knowledge and pedagogical competence. In addition, among socialization influences, former teachers received the highest mean score among the four socialization items, which is greater than the influence of family (M = 4.13) and friends (M = 3.95) in inspiring their career paths.

Furthermore, their wish to be a "positive influencer" (M = 4.31) and their "love for the English language" (M = 4.24) were much stronger than the thought of "always wanting to become a teacher" (M = 3.68). Even with this strong passion, they rated their English (M = 3.80) and teaching abilities (M = 3.76) at a moderate level. This means they know they need more university training. Finally, although they value job security (M = 4.12), students strongly disagreed with the idea of choosing this major as a "fallback career" (M = 2.54). Because this item has the lowest score, it suggests that their career choices are active and clear, not just a backup plan.

4.1.3. Correlations among Motivational Factors

Table 4.1.3

The correlations between different motivational factors

Constructs	1	2	3	4	5	6
1. Intrinsic Motivation	–	.723**	.494**	.588**	.495**	.541**
2. Altruistic/Social Utility Motivation	.723**	–	.496**	.636**	.495**	.488**
3. Extrinsic/Personal Utility Motivation	.494**	.496**	–	.563**	.420**	.535**
4. Perceived Ability	.588**	.636**	.563**	–	.303**	.417**
5. Task Demand and Task Return	.495**	.495**	.420**	.303**	–	.498**
6. Socialization Influences	.541**	.488**	.535**	.417**	.498**	–

*Note. **p < .01 (2-tailed)*

Pearson correlation analysis revealed that all six motivational constructs within the FIT-Choice model exhibit statistically significant positive correlations with one another (p <.01). This indicates that these motivational factors do not operate in isolation but are intricately intertwined, forming a cohesive psychological ecosystem in the students' career decision-making process.

The most striking finding is the robust positive correlation between Intrinsic Motivation and Altruistic/Social Utility Motivation (r = .723, p < .01). For EFL freshmen, personal passion for the language and the idealistic desire to contribute to society merge into one unified drive. The more they love the English language, the stronger their interest to use it as a tool to help

students and make a positive social impact. Furthermore, Perceived Ability also showed a strong positive relationship with Altruistic Motivation (r = .636) and Intrinsic Motivation (r = .588). This suggests that Students who reported higher perceived ability also tended to report stronger intrinsic and altruistic motivations.

4.2. Research question 2: To what extent do gender and prior informal teaching experience diflerentiate their motivational profiles?

4.2.1. Gender Differences in Career Motivation

Table 4.2.1

Descriptive Statistics of FIT-Choice Motivational Factors by Gender

Motivational Constructs	Male (n = 33)	Female (n = 68)	t	p
Intrinsic Motivation	4.24 (0.71)	3.86 (0.78)	2.403	**.018***
Altruistic/Social Utility Motivation	4.27 (0.85)	4.02 (0.85)	1.343	.182
Extrinsic/Personal Utility Motivation	3.84 (0.89)	3.48 (0.77)	2.104	**.038***
Perceived Ability	4.05 (0.85)	3.65 (0.82)	2.219	**.029***
Task Demand and Task Return	4.45 (0.51)	4.26 (0.65)	1.457	.148
Socialization Influences	4.24 (0.65)	4.09 (0.73)	1.035	.303

*Note. *p < .05*

Independent-samples t-tests were conducted to determine if demographic characteristics, specifically gender, create variations in career motivations. The results indicated statistically significant differences between male and female students in three specific domains.

Male freshmen exhibited significantly higher levels of Intrinsic Motivation (p = .018), Extrinsic/Personal Utility Motivation (p = .038), and Perceived Ability (p = .029) compared to their female counterparts. In a traditionally female-dominated major like English Pedagogy, male students who choose to pursue this path often equip themselves with a stronger intrinsic motivation and higher self-confidence to overcome underlying gender stereotypes. Additionally, driven by traditional societal expectations regarding financial provision, male students also display a more pragmatic concern for extrinsic rewards, such as salary and job security. Nevertheless, both genders share equally high levels of Altruistic Motivation and a realistic understanding of Task Demand (p > .05), proving that the core values of the teaching profession resonate universally across genders.

4.2.2 The Impact of Prior Teaching Experience: Passion and Academic Humility

Table 4.2.2

Descriptive Statistics of FIT-Choice Motivational Factors by Prior Teaching Experience

Motivational Constructs	Male (n = 33)	Female (n = 68)	t	p

Intrinsic Motivation	4.13 (0.69)	3.79 (0.84)	2.202	**.030***
Altruistic/Social Utility Motivation	4.25 (0.75)	3.90 (0.96)	2.056	**.042***
Extrinsic/Personal Utility Motivation	3.66 (0.82)	3.52 (0.84)	.832	.407
Perceived Ability	3.90 (0.72)	3.63 (0.98)	1.588	.115
Task Demand and Task Return	4.45 (0.51)	4.27 (0.63)	.739	.462
Socialization Influences	4.14 (0.66)	4.13 (0.76)	.060	.952

Note. $*p < .05$

Independent samples t-tests indicated significant differences based on prior teaching experience. Freshmen with prior experience demonstrated significantly higher Intrinsic Motivation ($p = .030$) and Altruistic Motivation ($p = .042$) than those without such experience. Initial interactions with learners successfully ignited their love for teaching and magnified their desire to become inspiring educators.

Most importantly, this practical experience did not foster complacency or an illusion of mastery. There was no significant difference in Perceived Ability ($p = .115$) between the experienced and inexperienced groups. This highlights a remarkable sense of academic humility among the freshmen. Despite having prior tutoring experience, they accurately perceive the vast gap between informal tutoring and professional classroom teaching. Consequently, they maintain a modest attitude, recognizing the necessity for rigorous, formal pedagogical training at the university level.

5. Discussion

5.1. Purpose

This study explored the career motivations of first-year English Pedagogy students at a public university in Ho Chi Minh City, while examining the influence of gender and prior teaching experience on these drives.

5.2. Findings

Although Task Demand and Task Return and Socialization Influences obtained the highest overall scores, the item-level analysis indicates that students were primarily attracted to teaching because of altruistic and intrinsic values rather than external rewards. This aligns with Tran and Cao (2020), emphasizing the role of passion and social contribution. It also indicates that modern EFL students actively and proudly choose this path. Interestingly, the results disagree with Tran et al. (2025), as Decree No.116 did not strongly influence their career choice, highlighting the students' genuine devotion to the profession. Demographically, male students showed significantly higher Intrinsic and Extrinsic motivations, as well as Perceived Ability. Moreover, freshmen with prior teaching experience had stronger passion, but their Perceived Ability stayed at a realistic, moderate level compared to inexperienced students.

5.3. Explanation for findings

These outcomes may be associated with the deep-seated cultural respect for the teaching profession. The high levels of Altruistic and Intrinsic motivation, together with participants' awareness of task demands, may indicate that students have some understanding of the profession's requirements rather than viewing it solely through an idealized lens. This pattern may suggest a more nuanced understanding of the profession, although further research would be needed to explore how such perceptions develop over time. Regarding gender, higher

motivation among males likely stems from the need to overcome stereotypes in a female-dominated major (Tran & Cao, 2020; Tran et al., 2025). Their extrinsic drive may be associated with societal expectations for financial stability. Finally, the impact of prior experience illustrates an increased awareness of professional knowledge; while tutoring fuels passion, students recognize the necessity of formal university training to bridge the gap between informal instruction and professional teaching.

5.4. Limitations

Despite providing valuable insights, this study has a few limitations. First, the self-reported data with small sample size (N = 101) from a single public university in Ho Chi Minh City means the findings should be interpreted with caution and may not be generalizable to all EFL teacher education students in Vietnam. Second, using a self-reported questionnaire can cause social desirability bias, as participants might unconsciously rate altruistic items higher to fit the noble image of a teacher. Lastly, the cross-sectional quantitative design only captures a snapshot of their current motivations and lacks the deep qualitative data needed to fully explain the psychological processes behind these choices.

5.5. Implications

Universities should introduce early practical opportunities, such as tutoring clubs, to sustain teaching passion. Faculties must support male students through mentorship programs and career talks featuring successful male educators. Future research should utilize qualitative or longitudinal methods to track how motivations evolve throughout the four-year curriculum.

Theoretically, the findings may contribute to the growing body of research applying the FIT-Choice framework in EFL teacher education contexts. The results also point to the potential influence of cultural and gender-related factors on career choice motivations, which could be explored further to enhance current theoretical explanations of why students choose teaching as a career.

5.6. Recommendations

Institutions should prioritize early-exposure initiatives to maintain freshmen's enthusiasm. Recruitment campaigns should emphasize social impact and personal fulfillment over financial incentives. Additionally, establishing mentorship for male students is crucial for gender inclusivity. Finally, freshmen should be encouraged to engage in informal teaching early to build a grounded professional identity and ensure long-term commitment.

6. Conclusion

This study investigated the initial career motivations of first-year English Pedagogy students at a public university in Ho Chi Minh City using the FIT-Choice framework, alongside the impacts of gender and prior teaching experience.

Findings reveal that freshmen are primarily driven by Altruistic and Intrinsic motivations, decisively rejecting teaching as a fallback career. Notably, male students exhibited higher motivation, potentially to overcome gender stereotypes, while those with prior tutoring experience demonstrated academic humility by recognizing the gap between informal tutoring and professional teaching.

However, generalizability is limited by a small sample size and potential social desirability bias. Future research should employ qualitative and longitudinal methods to track how these motivations evolve throughout the students' four-year academic curriculum and formal teaching practices.

#63 Vietnamese Students' Readiness for English as a Second Language: The Role of AI-Supported Learning Environments

Vu Thanh Loan[1]

Abstract

With the trend of English as a second language (ESL) as a major priority in Vietnam, students in universities are expected to use English in addition to the classroom more frequently than before. However, in a country that encourages widespread adoption of digital learning tools, this phenomenon may remain a hurdle as they tend to have difficulty in real-life ESL applications, leading to a significant discrepancy between what they learn and actual language use. Most previous studies have primarily focused on learners' motivation, perceptions, and attitudes toward AI-assisted language learning, while relatively little attention has been paid to the mechanisms through which AI-supported learning environments influence students' readiness to function in ESL-oriented contexts. The purpose of this study was to examine Vietnamese university students' ESL readiness and explore how AI-supported learning environments contribute to the development of such readiness through learner engagement and self-directed learning. A mixed-methods design was employed, incorporating survey data available from 70 university students as well as semi-structured interviews with 10 participants. Student engagement, self-directed learning, and use of English beyond the classroom were examined in this study. Quantitative data was analyzed using descriptive and inferential statistics and qualitative data were analysed thematically. A report on this survey found that this AI-driven learning experience increased student engagement and increased real-life English use, but the communicative competencies of the same students varied. This indicates that once implemented into pedagogy, AI can promote ESL readiness. This research needs context-sensitive utilization of AI in Vietnamese higher education.

***Keywords*:** AI-supported learning; ESL readiness; student engagement; real-world language use; Vietnamese higher education.

1. Introduction

Over the past few years, the country has been transitioning from learning English as a Foreign Language (EFL) to learning English as a Second Language (ESL), in which learners are learning not only linguistic concepts, but also how to speak English for the purposes of communicating in academic, professional, and social settings. This shift puts ever more pressures on learners' communicative effectiveness and their ability to interact with English extracurricularly. On the other hand, in many cases, Vietnamese university students still face challenges to use knowledge learned in teaching and writing classroom applications, indicating a disconnect between a language learning context and the real-life application of that language. However, with the exponential emergence of Artificial Intelligence (AI), the prospects of language learning have been opened up. For instance, chatbots, automated feedback systems, and adaptive learning platforms that utilize AI support have been demonstrated to foster learner engagement, autonomy, and self-regulated learning behaviors (Pan et al., 2024; Yang, n.d.). Studies show that AI can assist with language skill learning, as well as enhance learners' motivation and satisfaction (Shah et al., 2026; Thanh, 2025). In the Vietnamese case, learners show favourable attitudes toward AI-integrated language learning, especially related to enhanced speaking skills and discipline-specific English use (Pham et al., 2024; Quang &

[1] *Vu Thanh Loan, English Department, FPT University, Hanoi, Vietnam; Email:loanvt4@fe.edu.vn*

Minh, 2025). However, despite these encouraging findings, existing studies have predominantly examined learners' perceptions, technology acceptance, and discrete language-skill development, with limited attention to how AI-supported learning environments contribute to students' readiness to engage in authentic English use beyond classroom settings. In the present study, ESL readiness is conceptualized as a multidimensional construct encompassing learners' communicative confidence, self-directed learning capacity, willingness to communicate, and ability to use English meaningfully in authentic contexts. Additionally, the relationship of AI use, learner engagement and communicative competence has not been well investigated (Vistari & Yuliasri, 2026). To fill this gap, the current study (1) seeks to know the preparedness level of Vietnamese college students for L2 learning, (2) the influence of AI supported learning environment on English acquisition readiness, and (3) how use of AI relates to student engagement and language use at the level of the world language. The study aims to respond to the below research questions:

(1) How prepared does Vietnamese university students perceive themselves to be for English as a second language?

(2) How are AI learning environments contributing to the students' engagement and ESL readiness?

(3) What is the link between AI use and students' use of English outside the classroom? A further contribution of the study is finding out about how AI can assist the move from English as Foreign Language (EFL) toward English as Second Language (ESL) as language teaching in the Vietnamese higher education context.

2. Literature Review

2.1. Language Learning with the Assistance of AI in EFL/ESL Contexts

Artificial Intelligence (AI) was integrated into language education in the early 2020s, it altered the interaction between learners, content, teachers, and learning environment. AI-driven devices such as chatbots, automated writing appraisals, and adaptive learning systems offer immediate feedback, personalized learning trajectories, and more practice opportunities. These are the features that have been found to stimulate students' attention and to increase their involvement in language learning tasks (Pan et al., 2024; Wang et al., 2022). Indeed, AI tools can also simulate situations of authentic communication making language use practice in low-risk settings (which is particularly helpful in contexts where exposure to real language use is restricted). For example, it has also been shown through empirical studies that in the case of AI, it may be used to support some specific language learning activities. For instance, AI-powered applications have been found to enhance speaking skills by providing real-time feedback and interactive conversation practice (Giang et al., 2025). Similarly, AI-supported teaching can enrich reading understanding and self-controlled learning by scaffolding learners' participation in structured as well as adaptive tasks (Pan et al., 2024). These results imply that AI is not an additive but a transformative influence on language learning experiences. Engage learners, give autonomy, and integrate AI. An increasing amount of studies explore the potential of AI in promoting learner engagement and autonomy. Self-directed learning AI enabled environments sometimes promote self-directed learning, since students gain the ability to shape the speed and content as well as the mode of their activities. Such a pattern is consistent with research that is associated with the development of self-control, autonomy & independent learners via AI (Yang, n.d.). In addition, learners experience AI tools to be available to them and to provide support, which can motivate and enhance their motivation and willingness to perform language learning tasks (Alkandari, 2025). But engagement with AI-accommodated

contexts is not ubiquitous for learners. Although there exists an active use of such tools by some students to expand their vocabulary outside the classroom, there is also passive or limited use among the students. Based on a study conducted by Vistari and Yuliasri (2026) suggests that learners' attitudes mediate the association between AI use and communicative confidence, suggesting that positive attitudes may not automatically lead to language development. The findings underscore the need for examining not only whether students ultilize AI, but how students use it, in relation to language learning, and language outcomes.

2.2. AI in the Vietnamese Context

In recent years, there has been an increasing prevalence of AI-based language learning in Vietnam. The vast majority of university students accept the use of AI-based tools to enhance the usage of both of these and the perception of the positive effects on English as an EFL skill and learning efficiency is evidenced by previous research (Pham et al., 2024). It has been found that AI applications enhance learner satisfaction and perceived teaching usefulness in language learning environments (Thanh, 2025). Additionally, students had mentioned using AI in support of ESP, which implied that use of AI can assist language learning in a more focused and context-based and targeted way, thus it may assist ESL (Quang & Minh, 2025). However, such positive developments notwithstanding, issues persist in the successful application of AI applications to educational contexts. Problems like over-reliance and limitations in critical usage of, as well as access to, the AI, too much trust by students as well as a lack of access to the technology may hinder its effects. Additionally, the majority of other research in the Vietnamese context prior to that period has concentrated solely on students' perception and intention for learning in a Vietnamese context and less on learning behaviour or learning as an observable outcome.

2.3. ESL Readiness and Research Gap

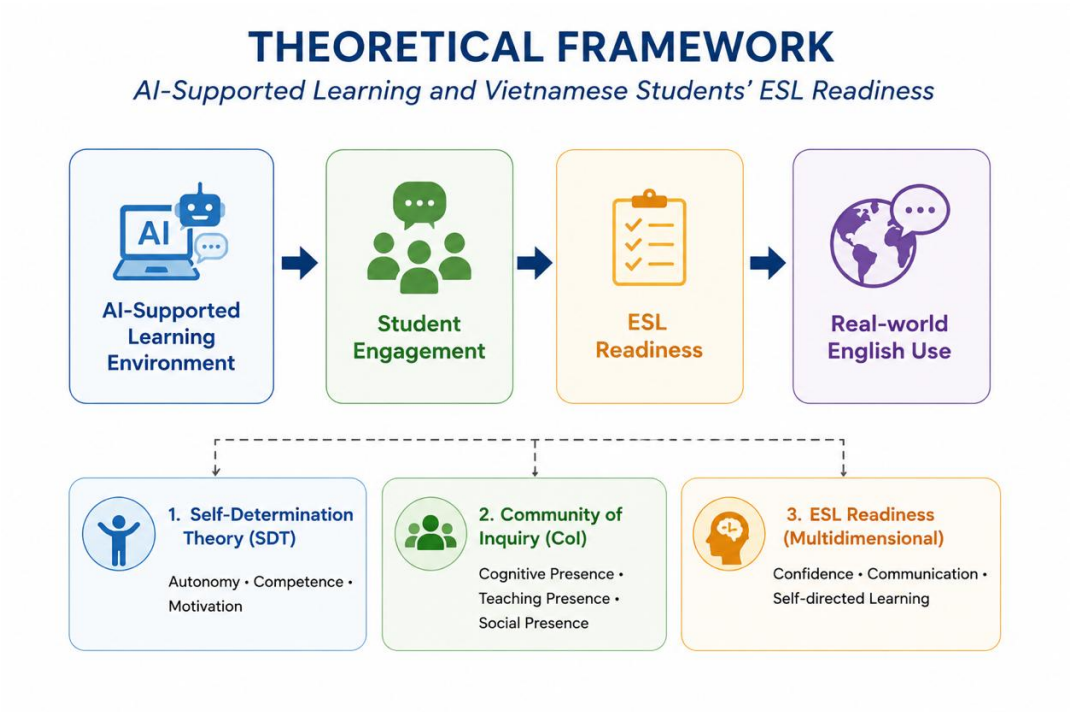
The idea of ESL readiness lies not only in learners' attitudes/ motivation, but also in how easily they can use English in the real world. This entails a blending of communicative skills, learner control, and ability to interact with English in a range of contexts. Although AI has been proven to support multiple facets of language learning, their role in advancing ESL readiness is less researched, especially in EFL-to-ESL transitioning environments like Vietnam. Moreover, prior work has not explored interaction of the use of AI, student engagement, and real-world language use as interrelated determinants of ESL readiness. This gap underscores the importance of a more rich study that takes into account the quantitative and qualitative aspects of students' experiences within the learning process. Beyond examining ESL readiness as an outcome variable, this study proposes that learner engagement serves as a critical explanatory mechanism through which AI-supported learning environments influence readiness for authentic language use. While previous studies have largely investigated direct relationships between AI adoption and language learning outcomes, the present study extends the literature by positioning engagement as a mediating construct linking technology use with communicative readiness. This perspective contributes to a more process-oriented understanding of AI-assisted language learning in EFL-to-ESL transition contexts.

2.4. Theoretical Framework

The integrated theoretical frameworks that support this study are Self-Determination Theory (SDT), Community of Inquiry (CoI) framework, and ESL readiness. In tandem, these viewpoints offer a basis for interpreting how AI-assisted learning environments are likely to play a role in enhancing students' readiness for English as a second language.

First, Self-Determination Theory (Deci & Ryan, 2000) indicates that learners are motivated and more engaged when their needs for autonomy, competence, and relatedness are satisfied. The study will investigate AI-facilitated language learning tools that can promote learner autonomy or provide on-demand feedback and support whenever students prefer, to ensure they are able to study at their own pace. Such features can enhance the feeling of competence and motivation of the learners toward language learning, which can drive more language learning.

Second, in the Community of Inquiry framework (Garrison et al., 2000), meaningful learning happens through the interplay between cognitive presence, social presence, and teaching presence. In AI-enabled learning environments, AI tools can support a cognitive presence by giving explanations, feedback, and chances to practice. Moreover, teachers are critical in shaping learning environments, which may encourage students to move into meaningful language use. On this view, AI acts as a facilitator, facilitating engagement instead of replacing human interaction.



Third, ESL readiness is not limited to language proficiency, but consists of learners' confidence, willingness to communicate, self-directedness to achieve their goals or use English in meaningful contexts. Readiness is accordingly a multidimensional construct indicating linguistic and behavioral readiness for English in the real world. Based on these theoretical constructs, the study argues that AI-enabled learning ecosystems will boost student engagement by promoting autonomy, capability, and cognitive input. That further increases engagement in turn contributes to improved ESL readiness and more frequent, meaningful use of English beyond the classroom. Unlike previous studies that primarily examined direct effects of AI use on language-learning outcomes, the present framework conceptualizes student engagement as a mediating mechanism that explains how AI-supported learning environments may facilitate ESL readiness and authentic language use. By emphasizing the process through which AI influences learning behaviours, the framework offers a more nuanced explanation of AI-assisted language learning outcomes. Therefore, this research proposes the relationship between the main variables as follows:

AI-Supported Learning Environment → Student Engagement → ESL Readiness → Real-world English Use

This framework guided the structure of our research questions, and both the quantitative and qualitative findings were interpreted accordingly.

Figure 1

Theoretical Framework

3. Methodology

3.1. Research Design

This study employs a mixed-methods design in order to investigate Vietnamese university students' English as a second language (ESL) readiness and the extent to which learning environments with AI support impact this. The combination of quantitative and qualitative methodologies allowed the study to identify generalizable trends as well as nuances of students' experiences. In particular, the quantitative one investigated relationships among relevant variables, while the qualitative one offered insights into how and why learners are using AI in language acquisition.

The study included 70 undergraduate students enrolled in English language courses at a private university in Vietnam. Participants took advantage of convenience sampling owing to accessibility and feasibility reasons. This was a very wide variety of students, with varying degrees of proficiency in language and learning style. As for the qualitative research, 10 participants were purposively sampled for the qualitative phase on the basis of their reported prevalence of AI usage (high users, medium users, and low users). This sampling approach facilitated a more balanced examination of different learner experiences and attitudes towards AI-driven language acquisition.

3.2. Instruments

Questionnaire

A standardized questionnaire was developed from the previous available literature on AI-supported language learning and ESL readiness. There were four main sections to the instrument:

Demographic Information (e.g., gender, major, years of learning English)

AI Usage (the frequency and purposes of using AI tools, such as chatbots, writing assistants, and translation tools)

Learner Engagement and Self-directed Learning (behavioral, emotional, and cognitive engagement)
ESL Readiness (confidence in communication, willingness to use English, and frequency of English use beyond the classroom)

Items were assessed using a five-point Likert scale (1 = strongly disagree to 5 = strongly agree). Two language education specialists reviewed content validity for the questionnaire.

Reliability Analysis

Cronbach's alpha coefficients were calculated for each construct to evaluate internal consistency. Results suggested acceptable to high reliability:

Table 1

Reliability of Scales (Cronbach's Alpha)

Construct	Number of Items	Cronbach's Alpha
AI Usage	5	0.81
Engagement	6	0.86
Self-directed Learning	5	0.83
ESL Readiness	6	0.88

All values of the measurement scales were above the minimum recommended value of 0.70, indicating good internal consistency and good reliability.

Interviews

Semi-structured interviews were carried out to probe in more depth into students' perceptions and experiences. A questionnaire that included the following questions was drawn up for the examination:

- How students can use AI tools in learning English?
- Perceptions of benefits and challenges to AI-driven learning?
- Influence of AI on engagement and confidence?
- Real-life experience of using English?

Data Collection Procedures

The data was collected during a 4-week period. The questionnaire was distributed via Google Forms and was voluntary. The participants were informed of the purpose of the study; the process of data collection was preceded by confidentiality and anonymity. Ten participants were invited for follow-up interviews following the survey.

Data Collection and Analysis

Analysis of all collected and coded data was carried out independently of prior research. The interviews (e.g., through Zoom, Google Meet) lasted approximately 20–30 minutes and were audio-recorded with consent of participants. The interviews were subsequently transcribed for analysis.

Quantitative Analysis

Quantitative data were analyzed with statistical software. Descriptive statistics (means and standard deviations) were used to summarize students' responses. By doing correlation

tests using Pearson correlation, inferential analysis was conducted to investigate relationships between AI use, engagement, and ESL readiness.

Qualitative Research Analysis

Qualitative analysis was conducted. Thematic analysis method was used to analyze the qualitative data. The analysis was performed using a systematic way:

(1) Familiarization with the data.

(2) Initial coding.

(3) Identification of themes and sub-themes.

(4) Theme refinement and interpretation. To lend credibility across themes, recurring patterns were compared and representative descriptions were used to reinforce each theme's credibility.

Ethical Considerations

The study was voluntary, and informed consent was given to all participants. The data were anonymized for confidentiality, and the right of the participants to withdraw at any time during the study was informed to them as well.

4. Results

4.1. Quantitative Findings

4.1.1. Descriptive Statistics

Table 2

Descriptive Statistics of Key Variables (N = 70)

Variable	Mean	SD	Level Interpretation
AI Usage Frequency	3.82	0.71	Moderately high
Student Engagement	3.76	0.65	Moderately high
Self-directed Learning	3.69	0.68	Moderate
ESL Readiness	3.58	0.72	Moderate
Real-world English Use	3.41	0.74	Moderately low

Descriptive statistics showed a stark difference in technology engagement vs actual language readiness. AI usage (M = 3.82) and engagement (M = 3.76) score relatively high, but ESL readiness (M = 3.58) and real-world English use (M = 3.41) lag behind. It indicates that regular use of AI tools does not imply proficiency in a foreign language. The gap of approximately 0.4 points between AI usage and real-world use points to a disconnect between digital practice and real-world application. And again, this is a classic example of an issue in EFL contexts that is transitioning to ESL, where one is exposed to the input language but without sufficient practice or confidence to use the language in situations outside of controlled situations. Also, the moderate level of self-directed learning (M = 3.69) indicates that AI tools offer independence while the students might not take the full advantage of these tools for further study. AIs may also serve task completion instead of the skill enhancement purpose which would reduce its impact at ESL readiness.

4.1.2. Correlation Analysis

Table 2

Correlations Between Key Variables

Variables	1	2	3	4
1. AI Usage	—			
2. Engagement	.52**	—		
3. ESL Readiness	.47**	.61**	—	
4. Real-world English Use	.39**	.55**	.63**	—

Note: p < .01

Correlation analysis sheds light on the relationships among variables. AI usage has a moderate correlation with engagement (r = .52) and ESL readiness (r = .47), suggesting AI plays a positive but not strong enough role to affect readiness in a direct manner. Interestingly, engagement has the most significant relation with ESL readiness (r = .61) and use of English in the real world (r = .55). As such, engagement seems to be an important mediating variable, connecting AI usage with language outcomes. In short, AI is effective only when it provokes learners to engage with its meaning. ESL readiness correlates with real-world English use most strongly (r = .63), indicating that readiness is related to real-world use of the language. However, the weaker correlation between AI usage and real-world use (r = .39) points to the fact that AI alone cannot foster a real use of language. Together, these results imply a three-layer relationship:

- AI leads to better engagement.
- Engagement enhances readiness.
- Readiness leads to real-world use.

The complex nature of this relationship supports the assertion that pedagogical mediation is vital to unlock AI's potential in language learning.

4.2. Qualitative Findings

Thematic analysis yielded three major themes with clearly defined sub-themes:

Table 3

Thematic Analysis of Students' Experiences with AI-Supported Learning

Theme	Sub-themes	Description	Representative Insights
1. AI as a Cognitive Support Tool	Instant feedback	AI provides quick corrections and explanations	Students rely on AI for immediate answers
	Vocabulary expansion	Exposure to new words and expressions	AI helps generate synonyms and ideas
	Task assistance	Support for writing and assignments	AI is used to complete tasks efficiently
2. AI-Driven Engagement and Confidence	Increased interest	Learning becomes more interactive and enjoyable	AI makes lessons less monotonous
	Reduced anxiety	Safe environment for practice	Students feel less afraid of making mistakes
	Perceived autonomy	Greater control over learning pace	Learners can study independently

3. Limited Transfer to Authentic Use	Passive dependence	Over-reliance on AI-generated responses	Students copy rather than produce language
	Lack of real interaction	Limited exposure to human communication	AI cannot fully simulate real conversations
	Low communicative confidence	Hesitation in real-life situations	Students feel unprepared outside class

Qualitative findings show that students mostly used AI as a cognitive support factor for making language learning more efficient. They frequently said they worked with such AI to proofread vocabulary, hone grammar and brainstorm ideas for assignments. This would lend credence to the idea that AI is a reinforcement of language input and task achievement, but more thorough analysis reveals a crucial trade-off in efficiency versus deep learning. Many students reported reliance on AI-generated responses without fully applying the language, suggesting a surface-level mode of engagement. This sheds light on the reason why frequently using AI did not always correlate with an increase in ESL readiness, that is, because less cognitive effort reduces the amount of time that learners are needed to sustain use and learn languages independently in the long haul. Besides cognitive assistance, AI was also used as a significant influence in forming the students' affective engagement. The learners felt more motivated and less anxious when responding to AI, largely as a result of a lack of judgment and social influence. The low-risk environment promotes frequent use of English and the feeling of working independently within the framework of learning. But this kind of participation seemed more affective than cognitive. Although they felt comfortable using English with AI, students were not routinely encouraged to think and act critically or make decisions on their own. Consequently the interaction generated by AI remained context-bound and did not fully equip learners with what was required for authentic communication. A less-obvious finding of it from the data is the scant link between AI-assisted learning and genuinely using language. Students noted a reliance on AI for responding, and also less confidence when they were expected to speak on their own. This indicates the emergence of what can be termed "assisted competence" where learners are effective on devices but lose in an unmediated environment. In AI-mediated contexts, the study lacks authentic interaction, negotiation of meaning, and real-time communicative competence, which is critical to ESL readiness. Collectively, the qualitative studies show that while AI does help to increase accessibility, motivation and learning efficiency, this does not lead to proper language use. How effectively AI serves to contribute to this shift from EFL to ESL depends upon the extent to which it integrates in pedagogies focused on active production, critical involvement as well as authentic communication with the learner.

5. Discussion

This research sought to reveal some insights about the readiness of Vietnamese university students towards English as a second language (ESL) and how AI-assisted learning experiences may contribute to this readiness. Findings contribute to provide considerable knowledge on the impact of AI on language learning experiences among the young Vietnamese learners in an EFL-to-ESL transitioning context. First, while students rated AI usage and involvement to be of average or higher, their ESL readiness (including real-world language use) was moderate. This result reveals an important inconsistency between technology-mediated and authentic language learning, also found in past studies. Even when AI software allows increased access to language input and practice opportunities, it does not necessarily result in the achievement of significant communicative competence. That points to the fact that exposure alone is not enough without opportunities for purposeful, natural language use. The

second is that this study confirms that learner engagement is at the center of this relationship between AI use and ESL readiness. The association between the engagement and both readiness and real-world language use shows that the best AI tools would benefit learners if they engage them in meaningful interaction. More importantly, the findings suggest that engagement functions as a mechanism rather than merely an outcome of AI-supported learning. This finding extends existing literature by demonstrating that the effectiveness of AI is contingent upon its capacity to foster meaningful learner engagement, which subsequently facilitates ESL readiness. Consequently, engagement should be viewed as a central explanatory construct in future models of AI-assisted language learning. This complements previous studies that have shown that engaging AI can improve engagement and self-regulated learning outcomes, when learners are actively engaged in learning (Pan et al., 2024; Yang, n.d.). However, the results add to this literature, revealing that AI use is not the only factor, but engagement is a critical means by which AI affects the process of language building. Third, the qualitative investigation also highlights that students adopt AI as a cognitive support service as opposed to as communicative experience. AI helps with vocabulary, grammar, and completing tasks but can also promote passive learning behaviors, such as excessive dependence on output. This finding also raises important questions regarding the distinction between assisted performance and independent communicative competence. While AI may enhance task completion efficiency, excessive reliance on AI-generated outputs may limit opportunities for productive language use and autonomous language development. This result also parallels recent concerns expressed in the literature that AI might potentially diminish learners' active language production when it is not judiciously guided (Vistari & Yuliasri, 2026). As a result, AI may appear to offer an uneven beneficial effect; lower-level skills may only be improved, while higher-level communicative competence might not be impacted at all. A second insight is of affective nature, specifically learners' confidence and anxiety. Because there was no social pressure to practice English with AI, students felt more comfortable practicing language with AI in a positive manner. But this approach can also risk providing a framework for a lack of exposure to the randomness and complexity of real human interaction. This finding shows us that, while the artificial intelligence has the potential to simulate human communication, it is not enough to recreate the social environment of authentic linguistic production (Wang et al., 2022). Taken together, these results suggest that pedagogically structured AI-supported learning environments must support the transition to ESL. Instead of being assistive tools, AI technologies ought to be integrated into tasks that have to do with active language production, collaboration and application of language in its entirety. This change means something especially in the Vietnamese context, since in the move towards ESL the learners need not only to learn to speak and write, but also learn to use what they know in different contexts. Finally, in expanding from perceptions to intentions to readiness and language actually used, this study complements existing research, enabling a more holistic exploration of AI in language education. It also emphasizes that the success of AI is determined not only by access and frequency, but rather requires an interaction quality as well as a pedagogical design.

6. Conclusion

The study analyzed the readiness of Vietnamese university students towards English as a second language (ESL), as well as the role of AI-supported learning contexts in shaping this preparedness. The results reveal that although students often adopt AI-supported tools and show reasonable enthusiasm, their readiness for authentic language usage is at best moderate. However, such is where gaps arise between the use of digital engagement and real-world English use; this gap is especially important in the transition from EFL to ESL contexts. The

evidence indicates that AI-supported learning could have positive effects on learner engagement, self-direction, and confidence. However, the connection with communicative competence and real-life language use is less stable. The results from quantitative and qualitative research suggest that students largely utilise AI as a support device for getting through assignments, but not to develop in-depth knowledge of the language. Moreover, an over-dependence on AI and absence of legitimate encounters will prevent transfer of the learning to real-life environments. These observations highlight the role of pedagogical mediation in AI integration. AI tools on their own cannot support ESL readiness; they play a crucial role in learning in organized activities that stimulate meaningful communication and active use of language. The study contributes to the growing body of AI-assisted language learning research by proposing a process-oriented perspective in which learner engagement functions as a mediating mechanism linking AI-supported learning environments and ESL readiness. This contribution extends existing studies that have primarily focused on direct relationships between AI use and learning outcomes. Furthermore, the study provides empirical evidence from the Vietnamese higher-education context, where the transition from EFL-oriented learning toward ESL-oriented communication presents unique pedagogical challenges.

Pedagogical Implications

According to the results of this research, AI use, when applied in English language teaching should look beyond a narrow focus on convenience or efficiency to a pedagogical purposive use of AI in ways which assist the learner in developing communicative competence. In the first place, instructors must design tasks that demand engagement of language production rather than completion with AI assistance. Rather than having learners base their responses on AI-generated responses, teachers can incorporate further activities like paraphrases, oral explanations, or peer discussions that force students to make their own language through process and reproduction. This transition is needed to close the gap between aided performance and readiness for ESL. Second, the study should position AI in the role of a guide for interaction rather than an answer generation device. To facilitate AI use, teachers can frame AI experiences around interactive tasks including role-plays, simulations, or problem-solving situations for students to negotiate meaning, respond in real-time, and maintain communication. As a consequence, AI becomes a facilitator of communicative practice rather than a replacement for it. Such an approach also helps to mimic more authentic use of language, which is essential in ESL-oriented contexts. Third, the research emphasizes the need to create balanced engagement, mixing affective comfort with cognitive challenge. As AI lowers anxiety and enhances motivation, too much dependence on low-risk interaction may deprive learners of the real communicative pressure. Teachers must therefore gradually walk students through transitioning from the AI environment to natural communication environments with humans including small group discussions, presentations, and group projects to build confidence and adaptability. Another important implication relates to the emergence of AI literacy and responsible usage. Students need explicit direction on how to use AI effectively for learning rather than dependency. This involves teaching them to critically analyze AI outputs, think critically about their learning, reflect on their process, and consider the use of AI as a supplementary tool for self-regulated education, and utilize AI as a learning aid for self-regulated learning. Without that kind of guidance, AI can instead enhance passive rather than active modes of learning and may perpetuate passive learning habits. At the curriculum level, the impact of AI should be discussed within the context of ESL-oriented instructional design, which relies on the use of technology to achieve wider learning objectives, such as real-world communicative skills, intercultural competence and lifelong learning. AI should not be an

afterthought, but part of a whole-learning-process which is coherent with the transition from EFL to ESL in Vietnam. Taken together, these implications suggest that the success of AI in language learning does not merely rely on its availability but on how AI is pedagogically orchestrated for meaningful, independent, and contextually sensitive language use.

Acknowledgments

The author would like to thank the students who took part in this study voluntarily and generously shared their experiences and perspectives regarding AI-supported language learning. In addition, appreciation is extended to the colleagues and experts who contributed with valuable feedback on the research design and data collection instruments. Their assistance and constructive comments were a major factor in the completion of the study. The author is solely responsible for the content of this paper and any errors that may remain.

#64 Bridging the Gap Between Classroom Learning and Real-World Communication in ESL: Curricula and Authentic Assessments

Trang Phan Thi Quynh[1]

Abstract

English is one of the most used languages in the world; however, in ESL classes, more time is given to grammar than to communication. This has led to a situation where ESL students know how to speak and write in English grammatically but cannot apply their knowledge in real-life situations. This study was conducted to solve this problem by designing a new ESL curriculum that emphasizes communication.

A mixed-methods, quasi-experimental design was employed with two groups of university students: an experimental group receiving instruction through communicative tasks and performance-based assessment, and a control group following a traditional approach. Data were collected through pre- and post-tests, questionnaires, interviews, and classroom observations.

The results indicate that the experimental group achieved significantly greater improvement in communicative competence, particularly in fluency and interaction. Qualitative findings also reveal increased learner confidence and engagement.

The study demonstrates that in ESL education, there is a need to transform from a test-based approach to a more student-centered approach in which learning is emphasized. This can be helpful in improving student learning in English and preparing them for an international environment.

***Keywords*:** ESL curriculum design, authentic assessment, communicative competence, real-world communication

1. Introduction

Today's global world is increasingly connected through technology and other means, and English is used in education, business, science, and technology. Because people from different cultures interact more than ever, speaking English fluently and effectively is no longer just a school subject—it is a vital skill needed to succeed in college and get a job. Because of this, universities around the world focus heavily on English language programs like English as a Second Language (ESL) and English as a Foreign Language (EFL). Their goal is to prepare students to communicate in real life. However, there is still a big gap between what these courses promise to teach and what actually happens inside the classroom.

Modern language education aims to help students build real communication skills. This means being able to use English smoothly and correctly in real-life situations (Usmonova, 2024). Yet, many English classrooms today still focus too much on grammar rules and memorizing word lists. These traditional teaching methods assume that if a student understands grammar rules, they will automatically be able to speak the language well. Recent studies show that this idea is wrong. To communicate well in real life, students need active practice, natural

[1] *University of Labor and Social Affairs (Campus 2)*

conversations, and a deep understanding of context. They cannot learn these skills through passive grammar drills (Usmonova, 2024).

This problem also shows up in the way students are tested. Traditional tests often use multiple-choice questions or fill-in-the-blank grammar tasks. While these tests are easy for teachers to grade, they only measure isolated grammar knowledge. They do not show whether a student can actually use the language to communicate in real-life situations (Panayides et al., 2025). Because of this, an odd problem happens: students get high scores on grammar tests, but they feel highly anxious, lack confidence, and freeze up when they try to speak English in real life.

To fix these issues, modern language experts suggest moving toward teaching methods that focus on communication and practical tasks (Get ready to mingle!, 2026). These methods use real-world, interactive activities—like group discussions, role-plays, problem-solving tasks, and practical writing exercises. These activities force students to practice real communication in English (Usmonova, 2024). However, even when teachers agree with these ideas, they often do not use them consistently. A major reason for this failure is that schools do not match their course goals (what is taught) with their teaching methods (how it is taught) and their tests (how it is graded) (Nikula et al., 2026).

Many global studies look at communicative teaching and real-world testing as separate ideas. There is little research on how to combine them into one system within a university course. This is a huge problem in developing education systems like Vietnam, which face fixed government rules, large classes, and traditional grammar tests. Because of this, simply copying Western teaching models does not work well.

This study fills this gap by testing a unique, fully aligned model for university English courses. What makes this framework new is that it directly connects three things: course goals, daily interactive tasks, and real-world tests. By showing how to match these parts to improve fluency, accuracy, coherence, and interaction, this paper goes beyond basic theory. It provides a practical blueprint to help universities overcome local challenges and build real-world communication skills.

The study is based on a quasi-experimental method, where one group of students is exposed to communicative learning and assessment, and another group is exposed to traditional methods. The study is based on learning outcomes and learning experiences.

The research for this study is informed by the following research questions:

1. To what extent does the integration of communicative activities and authentic assessment enhance the development of communicative competence in learners compared to the traditional approach?

2. What aspects of communicative competence develop best?

3. How do learners perceive the value of communicative activities and authentic assessment in terms of engagement, confidence, and learning effectiveness?

4. What differences can be observed in terms of interaction and participation in the classroom between the two approaches?

The purpose of answering these questions is to demonstrate how better alignment between teaching and assessment can lead to more effective communication for students in the English language. It also provides some practical suggestions for designing ESL courses that can effectively prepare learners for real-life communication.

2. Literature Review

2.1. Communicative Competence in Language Education

The concept of communicative competence has been the central idea in all the recent methods of language teaching. Communicative competence, first introduced by Dell Hymes in 1972, extends the concept of grammatical competence and means the ability to communicate in appropriate social contexts. But this concept has also been further developed by Michael Canale and Merrill Swain (1980) into the following elements: grammatical competence, sociolinguistic competence, discourse competence, and strategic competence. These elements also reveal the fact that communication does not only involve the use of correct language but also the ability to make sense out of the communication.

Though this framework has been largely accepted at a theoretical level, its practical application has been mixed at best. Many researchers have noted that the move to communicative language teaching (CLT) has been largely superficial and that form-focused instruction remains the norm (Jack C. Richards, 2006). In other words, communicative competence is largely an abstract concept and not yet a "operationalized" form of instruction.

Futhermore, recent studies show that while many schools state in their course descriptions that they want to teach communication skills, their actual classrooms tell a different story. Teachers still spend most of their time lecturing and focusing strictly on grammar rules (Usmonova, 2024). Because of this, communication skills are often treated as a nice theory on paper rather than a daily practice, leaving students unprepared for the real world.

2.2. Limitations of Traditional ESL Pedagogy

The conventional approach to ESL teaching has traditionally emphasized the importance of grammar teaching and vocabulary memorizing. Though such methods can be helpful for the acquisition of language knowledge, they have been accused of failing to encourage the use of language. In this regard, it has been argued by Claire Kramsch (1993) that language use cannot be separated from its contexts, and it cannot be developed without social interactions.

In addition to this, it has been observed that conventional methods assume a linear relationship between knowledge and use. This implies that if students are aware of the grammatical rules of a language, then they will be able to use it as well. However, it has been seen through research that this is not always true, and this has been identified as one of the primary flaws of form-focused methods, as it does not allow students to deal with the unexpected nature of communication. While these methods help students remember how the language works, actual research shows they do not help students speak naturally or spontaneously. Modern research in language learning confirms that language cannot be separated from real-life situations. Language skills are social by nature, meaning students can only truly build them by talking to others and working together to communicate (Getenet et al., 2026).

2.3. Assessment Practices and Issues of Validity

Assessment is one of the most important aspects in the development of teaching and learning. In many ESL environments, the assessment procedures continue to follow the conventional modes of teaching. Discrete point tests, such as multiple-choice questions and gap-fillings, are popularly used because they are easy and reliable. Nevertheless, these tests assess knowledge in isolated areas, not communicative ability (Lyle F. Bachman, 1990).

From a validity perspective, this poses some interesting concerns. If the aim of language learning is to promote communicative competence, then surely assessment must focus on the learner's ability to communicate. It has been stated by J. Charles Alderson (2005) that "if there is a poor match between learning goals and assessment strategies, then the potential impact of the entire curriculum can be seriously damaged." In this light, perhaps assessment strategies are not only measuring what really matters but are also leading teachers to focus on test preparation rather than promoting communicative competence.

Recent research warns that when a course aims to teach communication but uses basic grammar tests to grade students, it harms the quality of the whole educational program (Nikula et al., 2026).

2.4. Authentic Learning and Authentic Assessment

In response to the limitations of these traditional methods, there is increasing interest in the development of authentic learning and authentic assessment. This approach is based on the use of tasks that are similar to real-life communication, such as problem-solving tasks and group discussions. As noted by Grant Wiggins (1998), authentic assessment is based on the learners' ability to use their knowledge rather than their ability to recall the knowledge. Real-world testing measures a student's active ability to use all their language skills to achieve a practical goal, rather than their passive ability to repeat facts from a textbook (Panayides et al., 2025).

Authentic assessment is also believed to improve learner engagement and is effective for real-life communication. However, as noted earlier, the application of authentic assessment is challenging due to various limitations and constraints. For instance, most institutions are still using traditional methods of testing due to time and resource constraints. As such, authentic assessment is used in a limited manner to improve its effectiveness.

2.5. Synthesis and Research Gap

Previous research shows that while communication is the main goal of language learning, traditional classes and grammar tests fail to achieve it. Real-world tasks and practical testing work better, but schools rarely use them consistently.

The biggest gap in current research is the lack of connection between course goals, teaching methods, and testing. While Western studies look at these parts separately, very little research shows how to combine them into one system within Asian universities. This study fills that gap by testing a fully combined system. Instead of just suggesting communication tasks, this research proves how connecting goals, lessons, and tests directly improves student skills. To show this relationship, the framework is detailed below in Figure 1.

Figure 1

Alignment of curriculum, instructional practices, and assessment for the development of communicative competence

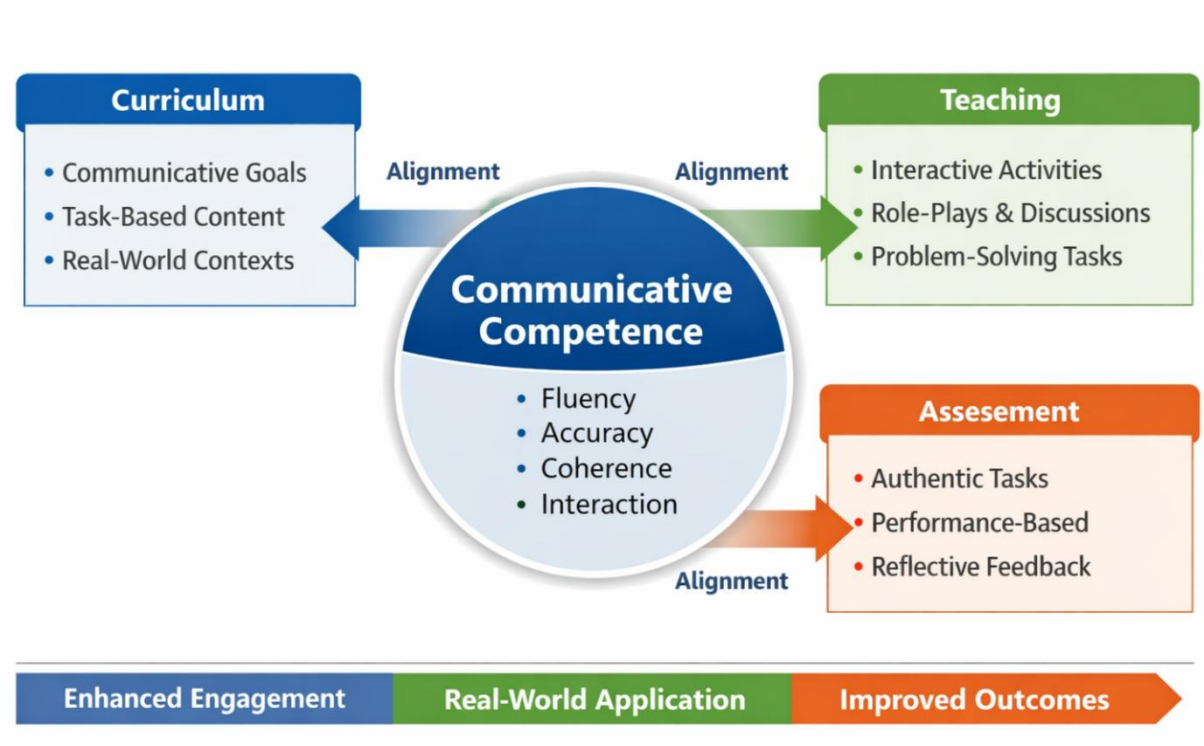

Figure 1 presents the conceptual framework that underpins this study, highlighting the need for alignment among curriculum design, instructional practices, and assessment in fostering communicative competence. At its core, the framework focuses on four key dimensions: fluency, accuracy, coherence, and interaction. It illustrates how curriculum objectives centered on real-world communication can be translated into classroom practice through communicative teaching strategies, including interactive tasks and problem-solving activities. These practices are further reinforced by authentic assessment approaches that measure learners' ability to use language in meaningful contexts. Overall, the framework suggests that learning is most effective when these elements are constructively aligned, resulting in greater student engagement and a stronger ability to apply language skills in real-life situations.

3. Methodology

3.1. Research Design

This study employs a mixed-methods research design to investigate the impact of integrating communicative activities with authentic assessment within an ESL curriculum. By combining quantitative and qualitative approaches, the study aims to provide a more comprehensive understanding of both students' learning outcomes and their classroom experiences.

More specifically, a quasi-experimental design is used, comparing a control group that receives traditional instruction with an experimental group that engages in a redesigned curriculum incorporating communicative tasks and authentic assessment practices. Quantitative data are collected to assess changes in students' communicative competence, while qualitative data offer deeper insights into learners' perspectives and the dynamics of classroom implementation. This approach is well suited to evaluating not only the effectiveness of the intervention but also how it is carried out in practice.

3.2. Participants

The study involves approximately 52 undergraduate students enrolled in an English course at a university. All participants are classified as having an intermediate level of English proficiency, based on institutional placement test results.

The students are divided into two groups. The control group (n = 26) follows a traditional instructional approach that emphasizes grammar and vocabulary, along with conventional assessment methods. In contrast, the experimental group (n = 26) is taught through a redesigned approach that incorporates communicative activities and authentic assessment tasks.

The demographic characteristics of the participants are presented in Table 1.

Table 1

Participant Demographics

Group	N	Gender (M/F)	Mean Age	English Level
Experimental	26	12 / 14	20.1	Intermediate
Control	26	11 / 15	20.3	Intermediate
Total	52	23 / 29	20.2	Intermediate

* Note. M = Male; F = Female.

All participants share comparable educational backgrounds and have studied English for a minimum of six years. Their involvement in the study is entirely voluntary, and ethical standards are carefully upheld, including the use of informed consent and the protection of participant confidentiality.

3.3. Instruments

To obtain a comprehensive set of data, the study employs multiple data collection instruments:

Pre-test and Post-test

Standardized speaking and writing assessments are administered before and after the intervention to evaluate changes in students' communicative competence. These tests are designed to reflect real-world communication tasks, such as expressing opinions, describing situations, and composing emails or brief reports.

Assessment Rubrics

Analytic rubrics are developed to assess students' performance in authentic tasks. They focus on key dimensions of communicative competence, including fluency, coherence, appropriateness, and task achievement.

Questionnaires

Structured questionnaires are distributed to students in the experimental group to explore their perceptions of the learning activities and assessment approaches. The instruments include both Likert-scale items and open-ended questions.

Classroom Observations

Classroom observations are conducted to document instructional practices, levels of student engagement, and patterns of interaction. Observation checklists are used to maintain consistency across sessions.

Interviews

Semi-structured interviews are carried out with a selected group of students and the instructor to gain deeper insights into their experiences, as well as the challenges encountered during the implementation of the redesigned curriculum.

3.4. Procedures

The study was carried out over a 10-week period and followed five main stages. Initially, a redesigned curriculum integrating communicative activities and authentic assessment was developed, and all research instruments were designed and pilot-tested. Pre-tests were then administered to both groups to determine baseline proficiency levels.

During the intervention, the control group received traditional instruction emphasizing grammar and vocabulary, whereas the experimental group participated in communicative activities, including discussions, role-plays, and problem-solving tasks, supported by authentic assessment. This phase was followed by post-testing to assess learning outcomes.

Subsequently, quantitative data from test scores were analyzed using paired and independent samples t-tests, while qualitative data from questionnaires, observations, and interviews were examined thematically to explore student engagement, perceptions, and communicative development.

4. Results

4.1. Overview of Findings

This section reports the findings of the study, with particular attention to the effects of integrating communicative activities and authentic assessment on students' communicative competence. The results are presented in two parts: (1) quantitative findings based on pre-test and post-test scores, and (2) qualitative findings derived from questionnaires, interviews, and classroom observations.

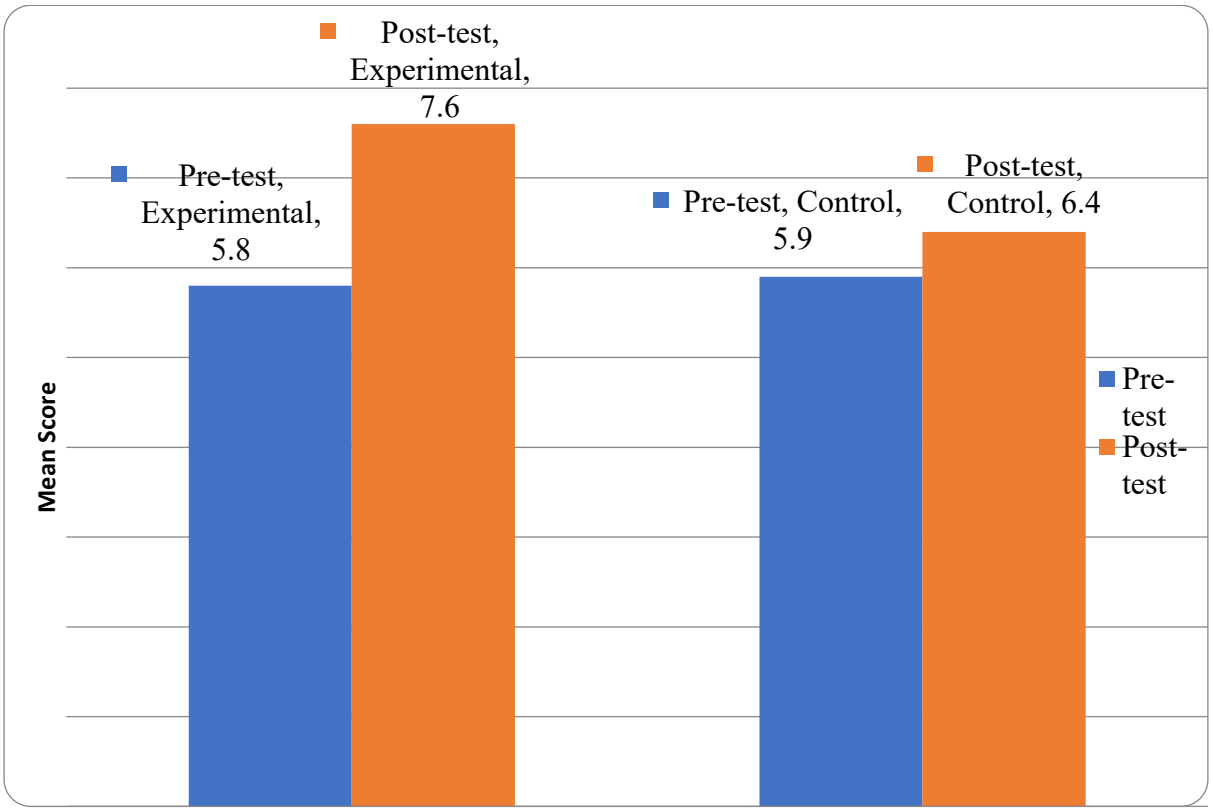
4.2. Quantitative Results

4.2.1. Pre-test and Post-test Comparison

Table 2 summarizes the mean scores and standard deviations for both the experimental and control groups in the pre-test and post-test.

Table 2

Pre-test and Post-test Scores of Experimental and Control Groups



Group	Test	Mean	SD	Gain
Experimental	Pre-test	5.8	0.72	—
	Post-test	7.6	0.65	+1.8
Control	Pre-test	5.9	0.75	—
	Post-test	6.4	0.70	+0.5

* Note. Gain = difference between post-test and pre-test scores.

The differences between pre-test and post-test scores are visually illustrated in Figure 2.

Figure 2

Pre-test and post-test comparison between experimental and control groups.

The findings indicate that both groups began the study with comparable levels of communicative competence. Following the intervention, however, the experimental group showed a marked improvement, increasing from 5.8 to 7.6, whereas the control group exhibited only a slight gain, rising from 5.9 to 6.4. These results suggest that the integration of communicative activities and authentic assessment had a more pronounced positive impact on students' performance.

4.2.2. Statistical Significance

To examine whether the differences observed were meaningful rather than due to chance, both paired-sample and independent-sample t-tests were applied. The outcomes of these analyses are summarized in Table 3.

Table 3

Results of t-tests for Pre-test and Post-test Comparisons

Comparison	t-value	p-value	Interpretation
Experimental (Pre-test vs Post-test)	8.45	< .001	Highly significant
Control (Pre-test vs Post-test)	2.10	< .05	Slightly significant
Post-test (Experimental vs Control)	5.72	< .001	Highly significant

* Note. Statistical significance set at $p < .05$.

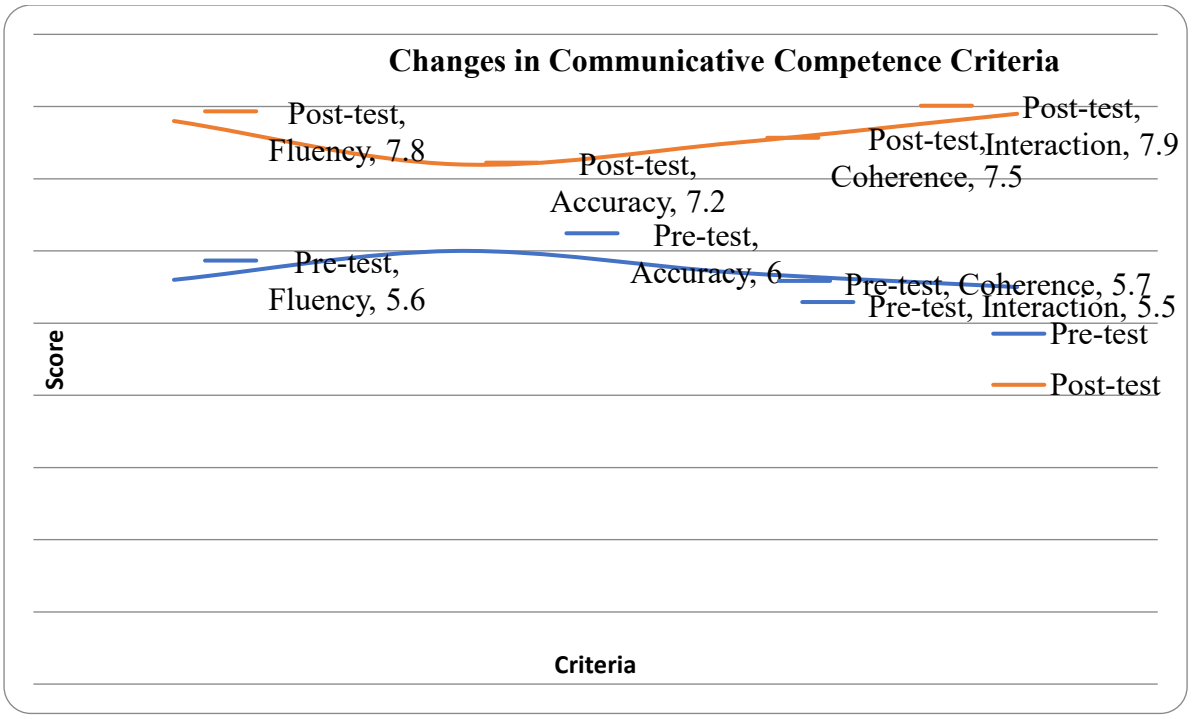
The results show that the experimental group improved to a much greater extent, with a highly significant difference ($p < .001$). In contrast, the control group made only a modest gain, although this change is still statistically significant ($p < .05$). In addition, the post-test comparison between the two groups reveals a significant difference, which supports the effectiveness of the intervention.

4.3. Performance by Communicative Criteria

To gain a clearer understanding of students' progress, their performance was assessed using specific criteria, including fluency, accuracy, coherence, and interaction. A detailed summary of results across these communicative aspects is presented in Table 4.

Table 4.

Mean Scores by Communicative Competence Criteria (Experimental Group)



Criteria	Pre-test	Post-test	Improvement
Fluency	5.6	7.8	+2.2
Accuracy	6.0	7.2	+1.2
Coherence	5.7	7.5	+1.8
Interaction	5.5	7.9	+2.4

* Note. Scores are based on analytic rubric ratings (scale 1–10).

The changes across communicative competence criteria from pre-test to post-test are illustrated in Figure 3.

Figure 3.

Changes in communicative competence criteria from pre-test to post-test.

The most noticeable gains are in interaction and fluency, indicating that the communicative activities were especially effective in helping students participate more naturally in real-time communication. While improvements in coherence and accuracy are also present, they are slightly less pronounced. This suggests that the intervention not only strengthened students' ability to communicate but also supported their overall language development.

4.4. Qualitative Results

4.4.1. Questionnaire Findings

The questionnaire results show that most students in the experimental group had positive responses to the new approach. A summary of their perceptions is provided in Table 5.

Table 5

Student Perceptions of Communicative Tasks and Authentic Assessment

Statement	Agreement (%)
Increased confidence in speaking English	85%
Tasks are more engaging than traditional methods	82%
Assessment reflects real communicative ability	78%
Improved readiness for real-world communication	80%

* Note. Percentages represent students who selected "Agree" or "Strongly Agree."

These results suggest that authentic activities do more than improve performance; they also boost students' motivation and confidence, both of which play a crucial role in successful language learning.

4.4.2. Interview Insights

The semi-structured interviews offered a deeper understanding of students' experiences, revealing several key themes.

- Students appreciated the practical relevance of tasks (e.g., writing emails, participating in discussions).
- Many reported feeling more prepared for real-life communication.
- Some students initially found the tasks challenging but gradually became more comfortable.

These responses suggest that although authentic tasks can take some time for students to get used to, they ultimately promote meaningful learning and help develop practical language skills.

4.4.3. Classroom Observations

Classroom observations revealed notable differences between the two groups:

- The experimental group demonstrated higher levels of participation and interaction.
- Students were more willing to express ideas and engage in discussions.
- The control group showed more passive learning behaviors, focusing mainly on completing exercises.

These observations align with the quantitative results, emphasizing the important role of communicative activities in fostering active learning and increasing student engagement.

4.5. Summary of Results

Overall, the findings suggest that incorporating communicative activities and authentic assessment into the ESL curriculum leads to clear improvements in students' communicative competence. The experimental group not only achieved higher test scores than the control group but also showed greater confidence, stronger engagement, and a better ability to use language in real-life situations. These results offer strong support for the value of aligning teaching practices with authentic assessment approaches.

5. Discussion

5.1. Overview of Key Findings

The results of this study show that integrating communicative activities with authentic assessment has a clear positive effect on students' communicative competence. Compared to the control group, the experimental group made greater overall progress, especially in fluency and interaction. In addition, the qualitative findings point to higher levels of confidence, stronger engagement, and a greater sense of relevance in the learning tasks. Taken together, these results suggest that designing instruction around real-world communication needs can improve both students' language performance and their overall learning experience.

5.2. Alignment with Communicative Competence Theory

The findings of this study provide strong support for the concept of communicative competence first introduced by Dell Hymes (1972) and later expanded by Michael Canale and Merrill Swain (1980). The noticeable progress in learners' fluency, coherence, and ability to interact suggests that they were not just learning grammatical rules, but were becoming more capable of using the language in real-life situations. This reinforces the idea that communicative competence is made up of several interconnected elements and cannot be fully achieved through a sole focus on form.

In addition, the clear improvement in interactional skills underlines how important it is to give learners chances to communicate meaningfully. This aligns with the perspective of Claire Kramsch (1993), who emphasizes the social and contextual nature of language learning. Through engaging in authentic tasks, learners were able to negotiate meaning, respond to real communicative needs, and gradually build their awareness of how language is used in different contexts.

5.3. Implications for ESL Pedagogy

The findings also highlight several limitations of traditional ESL teaching methods. As suggested in earlier research, form-focused instruction often assumes that grammatical knowledge will automatically translate into communicative ability. However, the relatively modest progress observed in the control group indicates that this is not always the case in practice. This supports the view of Jack C. Richards (2006), who argues that traditional approaches alone may not be sufficient for developing real-world communication skills.

In contrast, the stronger results achieved by the experimental group point to the effectiveness of communicative language teaching (CLT), particularly when combined with authentic tasks. Engaging in activities that reflect real-life situations appears to encourage greater participation and more meaningful use of language. Interestingly, the improvement in both fluency and accuracy suggests that communicative approaches do not come at the

expense of linguistic development; instead, they seem to support it in a more integrated and balanced way.

5.4. The Role of Authentic Assessment

A key contribution of this study is its focus on authentic assessment and how it influences learning. The results make it clear that assessment is not just a way to measure outcomes—it also shapes the way students approach learning itself. As Lyle F. Bachman (1990) points out, an assessment is only truly valid if it reflects how language is used in real-life situations. In this study, performance-based tasks seemed to capture students' communicative abilities more effectively than traditional tests, which often focus more on isolated knowledge.

Students' reactions further support this point. Many of them appeared more engaged and confident when they were given opportunities to demonstrate what they could actually do with the language. This idea is consistent with Grant Wiggins (1998), who emphasizes the importance of meaningful assessment that goes beyond memorization. That said, applying this type of assessment is not without difficulties. It often demands more time, careful planning, and proper training for teachers. Because of these practical constraints, its use in everyday classrooms may still be somewhat limited, even though its benefits are quite clear.

5.5. Addressing the Curriculum–Assessment Gap

A recurring concern in the literature is the gap between what a curriculum is designed to achieve and how students are actually assessed. J. Charles Alderson (2005) highlights this issue, and the findings of this study seem to confirm it. At the same time, they also suggest a practical way to address the problem. When communicative activities were combined with authentic assessment, the revised curriculum appeared to bring learning objectives and evaluation practices into closer alignment.

Even so, alignment by itself does not guarantee success. For this approach to work effectively, it needs careful planning, clear and transparent assessment criteria, and ongoing support for teachers. Without these conditions in place, communicative methods may be applied unevenly or only at a surface level, which can reduce their overall impact.

5.6. Critical Reflection and Limitations

Although the findings are encouraging, a number of limitations need to be taken into account. To begin with, the intervention was carried out over a relatively short period of time, which makes it difficult to determine whether the observed improvements would be sustained in the long run. In addition, the study involved a fairly specific group of university students, so the results may not easily apply to other contexts or learner populations. It is also worth noting that the success of the intervention likely depended, at least in part, on the teacher's experience and the particular classroom environment, meaning that similar approaches could produce different outcomes elsewhere.

Another point to consider is that, while the study highlights the value of authentic assessment, it does not fully address some of the practical challenges teachers face. Issues such as large class sizes, institutional expectations, and the pressure of standardized testing can make it difficult to implement communicative approaches consistently. These constraints remain important obstacles and help explain why such methods are not always widely adopted in practice.

5.7. Implications for Future Research

Future research could usefully look at the longer-term effects of combining communicative activities with authentic assessment, especially across a wider range of educational settings. It would also be helpful to explore how teachers can be better supported in applying these approaches in their own classrooms, particularly in contexts where resources are limited. In addition, including learners from different backgrounds and proficiency levels could offer a broader view of how well this framework works in practice.

Taken together, this study adds to the growing body of research that supports the use of communicative teaching alongside authentic assessment in ESL education. By considering not only the strengths but also the challenges of this approach, it offers a more balanced perspective on how language programs can be designed to better equip learners for communication beyond the classroom.

6. Conclusion

6.1. Conclusion

This study set out to explore whether combining communicative activities with authentic forms of assessment could improve learners' communicative competence in ESL settings. The findings suggest that when teaching is closely connected to real-world communication, students tend to show noticeable progress, particularly in terms of fluency, interaction, and their overall ability to use the language effectively.

At the same time, the results draw attention to a gap that still exists in many ESL programs. Although communicative competence is often emphasized in curriculum goals, classroom practices do not always reflect this priority. More traditional methods of teaching and assessment remain quite common, and this can make it harder for learners to turn what they know about the language into actual communication. In contrast, the curriculum used in this study shows that when teaching and assessment are more carefully aligned, students are better able to use language in realistic situations.

The study also highlights the need to move beyond approaches that focus mainly on grammar and isolated forms. A more balanced approach—one that brings together language use, context, and interaction—seems to be more effective. Tasks that reflect real-life communication not only help students develop their skills but also appear to increase their confidence, motivation, and level of engagement. Taken together, these findings suggest that language teaching is most effective when it focuses on meaningful communication rather than treating language as a set of separate rules to be learned.

6.2. Policy Implications

The findings of this study have several implications for language education, particularly in terms of policy, curriculum design, and classroom practice.

At the curriculum level, the results point to the need for closer alignment between learning goals, teaching approaches, and assessment. It is not enough for programs to simply state that communicative competence is the objective; this aim needs to be clearly reflected in how lessons are designed and how students are evaluated. In this sense, authentic tasks should not be treated as optional add-ons, but rather as a central part of the curriculum.

From an assessment perspective, the study also raises questions about the continued reliance on traditional testing formats. While standardized tests are convenient and allow for easy comparison, they do not always capture how well learners can actually use language in

real-life situations. For this reason, there is a strong case for incorporating more performance-based and authentic forms of assessment that provide a fuller picture of students' communicative abilities.

Teacher development is another key area to consider. The success of communicative and authentic approaches depends heavily on how well they are implemented in the classroom. This means teachers need appropriate training and ongoing support, particularly in designing meaningful tasks, applying suitable assessment criteria, and managing interactive learning environments. Without this kind of preparation, even well-designed programs may fall short in practice.

At the same time, practical constraints at the institutional level cannot be overlooked. Large class sizes, limited teaching time, and restricted resources can all make it difficult to apply these approaches consistently. Institutions therefore need to create conditions that allow for flexibility and innovation, while still maintaining academic standards.

Finally, at the policy level, there is a need to move toward a more balanced view of language assessment—one that values not only grammatical accuracy but also the ability to communicate effectively. This may involve rethinking existing assessment systems so that they better reflect the kinds of language skills learners actually need outside the classroom.

6.3. Final Remarks

In closing, this study highlights the ongoing need to connect classroom learning more closely with the way language is used beyond academic settings. The results indicate that combining communicative activities with authentic assessment can have a real impact on how effectively learners develop their language abilities. Beyond its theoretical contribution, the study also offers some practical insights that may help improve current approaches to ESL teaching.

Going forward, meaningful improvement will require consistent effort across different areas, from curriculum planning to classroom implementation and broader educational policy. A more coordinated approach in these areas can better equip learners with the skills they need to communicate confidently in an increasingly interconnected world.

Acknowledgments

The author would like to express sincere gratitude to the students who participated in this study for their time, cooperation, and willingness to engage in the research activities. Their active involvement and honest feedback played an important role in shaping the findings of this study.

Special thanks are also extended to the colleagues and instructors at the University of Labor and Social Affairs (Campus 2) for their support during the implementation of the research. Their assistance in facilitating classroom activities and providing valuable insights is greatly appreciated.

The author is also grateful to those who contributed to the development of the research instruments and provided feedback throughout the research process. Their input helped improve the quality and clarity of the study.

Finally, the author would like to acknowledge the institutional support that made this research possible.

Notes

1 ESL refers to learners studying English in non-English-speaking contexts; communicative competence includes fluency, accuracy, coherence, and interaction (based on Dell Hymes; Michael Canale & Merrill Swain).

2 The study was conducted over a 10-week period with voluntary participation and ensured confidentiality.

Phan Thị Quỳnh Trang is a lecturer at the University of Labor and Social Affairs (Campus 2), Vietnam. She holds a Master's degree in English Teaching Methods and has 18 years of experience in teaching English at the tertiary level. Her research interests include communicative language teaching, ESL curriculum design, and authentic assessment. She focuses on bridging the gap between classroom instruction and real-world communication, with an emphasis on improving learners' communicative competence. She has been actively involved in teaching and curriculum development and is committed to enhancing student-centered learning practices in English language education.

Appendices

Appendix A

Sample Communicative Tasks Used in the Experimental Group

Task 1: Group Discussion

Topic: The impact of social media on communication.

Students discuss in groups and respond to peers' ideas.

Task 2: Role-play Activity

Students perform real-life situations such as job interviews, customer service, or travel scenarios.

Task 3: Problem-solving Task

Students propose solutions to issues (e.g., reducing plastic waste on campus).

Task 4: Real-world Writing

Students write emails (job application, complaint response, or inquiry).

Appendix B

Analytic Assessment Rubric for Communicative Competence

Each criterion is rated on a 10-point scale. Descriptors are provided to ensure consistency in evaluation.

1. **Fluency**
   Ability to speak smoothly and maintain the flow of communication

Score Range	Descriptor
1–2	Speech is very slow, with frequent pauses; unable to maintain communication
3–4	Frequent hesitation; ideas are difficult to express continuously
5–6	Some hesitation, but able to communicate basic ideas
7–8	Generally fluent with occasional pauses; ideas expressed clearly
9–10	Speaks smoothly and naturally with minimal hesitation

2. **Accuracy**
   Correct use of grammar, vocabulary, and sentence structures

Score Range	Descriptor
1–2	Frequent errors that make understanding difficult
3–4	Many errors; meaning sometimes unclear
5–6	Some errors, but meaning is generally understandable
7–8	Minor errors that do not affect communication
9–10	Accurate use of language with very few errors

3. **Coherence**
   Clarity, organization, and logical flow of ideas

Score Range	Descriptor
1–2	Ideas are disorganized and difficult to follow
3–4	Limited organization; weak connections between ideas
5–6	Some organization; ideas are partially clear
7–8	Well-organized with clear progression of ideas
9–10	Highly coherent; ideas are logically and effectively connected

4. Interaction
Ability to engage in communication and respond appropriately

Score Range	Descriptor
1–2	Rarely responds; unable to maintain interaction
3–4	Limited participation; responses are minimal
5–6	Participates but with limited engagement
7–8	Actively participates and responds appropriately
9–10	Highly interactive; initiates and sustains communication effectively

Appendix C

Student Questionnaire on Communicative Competence and Authentic Assessment

Instructions

Please answer all questions honestly. There are no right or wrong answers. Your responses are confidential and used for research purposes only.

Part 1: Background Information (Multiple Choice)

1. Gender:

☐ Male ☐ Female ☐ Other

2. Years of learning English:

☐ Less than 5 years ☐ 5–7 years ☐ More than 7 years

3.Self-rated English level

☐ Beginner ☐ Elementary ☐ Intermediate ☐ Upper-intermediate ☐ Advanced

Part 2: Communicative Competence and Learning Experience

Scale:

1 = Strongly Disagree | 2 = Disagree | 3 = Neutral | 4 = Agree | 5 = Strongly Agree

Section A: Communicative Competence Development

Fluency

No.	Statement	1	2	3	4	5
4	I can speak English more smoothly than before.	☐	☐	☐	☐	☐
5	I can express my ideas without frequent pauses.	☐	☐	☐	☐	☐
6	I can maintain speech for a longer time without difficulty.	☐	☐	☐	☐	☐

Accuracy

No.	Statement	1	2	3	4	5
7	I use grammar more accurately when speaking English.	☐	☐	☐	☐	☐
8	I can choose appropriate vocabulary when communicating.	☐	☐	☐	☐	☐
9	My errors do not significantly affect my communication.	☐	☐	☐	☐	☐

Coherence

No.	Statement	1	2	3	4	5
10	I can organize my ideas clearly when speaking or writing.	☐	☐	☐	☐	☐

11	My ideas are logically connected when I communicate.	☐	☐	☐	☐	☐
12	I can explain my thoughts in a structured way.	☐	☐	☐	☐	☐

Interaction

No.	Statement	1	2	3	4	5
13	I can respond appropriately during conversations.	☐	☐	☐	☐	☐
14	I actively participate in discussions with others.	☐	☐	☐	☐	☐
15	I can maintain a conversation with my classmates.	☐	☐	☐	☐	☐

Section B: Confidence in Communication

No.	Statement	1	2	3	4	5
16	I feel more confident speaking English in class.	☐	☐	☐	☐	☐
17	I feel comfortable expressing my opinions in English.	☐	☐	☐	☐	☐
18	I am less afraid of making mistakes when speaking English.	☐	☐	☐	☐	☐
19	I feel prepared to use English in real-life situations.					

Section C: Authentic Assessment

No.	Statement	1	2	3	4	5
20	The assessment tasks reflect real-life communication.	☐	☐	☐	☐	☐
21	I can demonstrate my actual ability through these tasks.	☐	☐	☐	☐	☐
22	The assessment methods are fair and appropriate.	☐	☐	☐	☐	☐
23	I understand how my performance is evaluated.					

Section D: Engagement and Learning Experience

No.	Statement	1	2	3	4	5
24	The activities are more interesting than traditional lessons.	☐	☐	☐	☐	☐
25	I am motivated to participate in communicative tasks.	☐	☐	☐	☐	☐

26	I enjoy working with classmates during activities.	☐	☐	☐	☐	☐
27	The tasks encourage me to use English actively.	☐	☐	☐	☐	☐
28	I feel more engaged in this class compared to other English classes.	☐	☐	☐	☐	☐

Part 3: Learning Preferences

29. Which activity helped you most?
☐ Group discussion ☐ Role-play ☐ Problem-solving task ☐ Writing tasks ☐ Other: _____

30. Which skill improved the most?
☐ Speaking ☐ Listening ☐ Writing ☐ Vocabulary ☐ Grammar

31. What type of assessment do you prefer?
☐ Traditional tests ☐ Performance-based tasks ☐ Combination of both

Part 4: Open-ended Questions

32. Which activity helped you most in improving your communication skills? Why?
.....

33. What challenges did you face during the course?
.....

34. What suggestions do you have for improving the course?
.....

Appendix D

Participant Instructions

You will participate in classroom activities designed to improve your communication skills.

You are encouraged to actively engage in discussions, role-plays, and group tasks.

There are no “right” or “wrong” answers—focus on expressing your ideas clearly.

All responses will be kept confidential and used only for research purposes.

Appendix E

Participant Demographic Information

Total participants: 52 undergraduate students

Age range: 19–22 years

English level: Intermediate

Years of learning English: Minimum 6 years

Groups: Experimental (26), Control (26)

Appendix F

Student Questionnaire on Communicative Activities and Authentic Assessment

Instructions:

Please read each statement carefully and indicate your level of agreement. Your responses will be kept confidential and used only for research purposes.

Scale:

1 = Strongly Disagree

2 = Disagree

3 = Neutral

4 = Agree

5 = Strongly Agree

Section A: Perceived Improvement

No.	Statement	1	2	3	4	5
1	The communicative activities helped me improve my speaking skills.	☐	☐	☐	☐	☐
2	I am better able to express my ideas in English after this course.	☐	☐	☐	☐	☐
3	My fluency in English has improved.	☐	☐	☐	☐	☐
4	I can interact more confidently with others in English.	☐	☐	☐	☐	☐
5	I can organize my ideas more clearly when speaking or writing.	☐	☐	☐	☐	☐

Section B: Engagement and Motivation

No.	Statement	1	2	3	4	5
6	The activities in this course are more interesting than traditional lessons.	☐	☐	☐	☐	☐
7	I feel more motivated to participate in class.	☐	☐	☐	☐	☐
8	I enjoy working with my classmates during communicative tasks.	☐	☐	☐	☐	☐
9	The tasks encourage me to use English actively.	☐	☐	☐	☐	☐

Section C: Authentic Assessment

No.	Statement	1	2	3	4	5

10	The assessment tasks reflect real-life communication.	☐	☐	☐	☐	☐
11	I understand how my performance is evaluated.	☐	☐	☐	☐	☐
12	The assessment methods are fair.	☐	☐	☐	☐	☐
13	I can demonstrate my actual ability through these tasks.	☐	☐	☐	☐	☐

Section D: Confidence and Learning Experience

No.	Statement	1	2	3	4	5
14	I feel more confident using English in real-life situations.	☐	☐	☐	☐	☐
15	I am less afraid of making mistakes when speaking English.	☐	☐	☐	☐	☐
16	I feel more prepared for real-world communication.	☐	☐	☐	☐	☐

Section E: Open-ended Questions

17. Which activity did you find most useful? Why?

……..

18. What difficulties did you experience during the course?

……..

19. What suggestions do you have for improving the course?

……..

#65 Aviation English Majors' Perceptions of the Use of AI-based Language Learning Tools for Self-regulated English Speaking Practice

Thị Nguyệt Ánh Nguyễn[1], Thị Ngọc Quý Nguyễn[2]

Abstract

Artificial Intelligence (AI) has been proved to radically enhance the quality and personalization of language education. Motivated by the growing integration of AI technologies into English learning and the need for research on learners' perceptions of their effectiveness, this study investigated how tertiary English majors perceived the application of AI-based language learning tools in English speaking self-practice. Employing a quantitative research method, the study was conducted with the participation of 161 students specializing in Aviation English at Vietnam Aviation Academy. Quantitative data on the participants' perceptions of using AI-powered software for self-regulated English speaking practice were collected using online questionnaires. The results showed that most participants strongly agreed that AI-enhanced resources provided them with personalized learning experiences and real-time feedback. However, they also identified drawbacks, including technical issues and the limited real-life applicability of examples generated by the applications. More importantly, the research detailed specific benefits and limitations of each tool investigated, as perceived by the students. These findings are expected to help any students who wish to improve their English speaking competence choose the AI software that best suits their needs and conditions to achieve their targeted goals in English learning.

***Keywords*:** AI tools, English speaking skills, language learning tools, self-regulated

1. Introduction

With the emergence of AI technologies, various English learning tools have been developed to facilitate English acquisition. These AI tools are quickly adopted by individuals and businesses worldwide for professional and personal growth (De La Vall & Araya, 2023). Given their popularity, AI tools have become one of researchers' primary concerns. Numerous research has examined the use of AI in various English learning aspects, including impacts and challenges of AI-integrated English learning (Nguyen, 2024; Quyet et al., 2024), teachers' perceptions of AI's role in language teaching (Benek, 2025; Hieu et al., 2024; Nguyen, 2024), learners' attitudes towards and experiences in using these applications (Nguyen, 2024; Benek, 2025; Nguyen & Le, 2025). Among the learners' perception-based studies, the majority were devoted to explore either learners' views on general English learning or on specific skills like writing (Thao et al., 2024). Quite few studies explored learners' perceptions of using these tools specifically for self-regulated speaking practice, however.

This study aimed to address the aforementioned research gap by exploring how Vietnam Aviation Academy (VAA) students majoring in Aviation English (AE) perceived the benefits and constraints of AI-integrated autonomous English speaking practice. It is anticipated that the research findings will provide valuable insights for AE students seeking to leverage these applications for their targeted speaking improvement.

2. Literature Review

2.1. English speaking skills

Speaking skills are important in language acquisition. Effective oral communication correlates positively with academic achievement, facilitates cultural exchange and serves as a primary gateway to global knowledge (Grain et al., 2022). More importantly, good speaking proficiency is a critical determinant of career prospects, especially in aviation industry, where English serves as the standard language for customer service and passenger communication (Tangniam, 2006). Despite the critical importance of English speaking proficiency, many students continue to face significant challenges in achieving their targeted speaking goals. Determinants of suboptimal speaking performance are multifaced, encompassing not only linguistic constraints like restricted vocabulary, mispronunciation, insufficient grammar knowledge (Nhan, 2024), but also affective, environmental factors like anxiety, demotivation, fear of making mistakes (Mai et al., 2024).

Self-learning has emerged as a solution to the aforementioned constraints (Tuan, 2021). This learning mode – learners' ability to take responsibility for their learning by setting goals, selecting strategies and evaluating progress on their own (Holec, 1981) – gives learners greater control over their learning process (Buitrago, 2017). As technology develops, AI-based language learning tools become potential in providing additional ways learners can employ to improve their speaking abilities independently and efficiently (Rusmiyanto et al., 2023).

2.2. AI-based language learning tools

AI technology refers to the capability of computer systems to carry out tasks in relation to human intelligence (Russell & Norvig, 2022). The incorporation of AI in education helps create more interesting educational experiences (Lampou, 2023). AI-based language learning tools are products of such incorporation. They are computer programs, software or platforms that use AI to help with language learning (De La Vall & Araya, 2023).

The benefits of AI tools have been well documented, showing their facilitative role in English acquisition. First, AI-powered language learning software excels at personalizing learning (De La Vall & Araya, 2023). The software can identify areas requiring additional practice and improvements; then recommend customized lessons and provide exercises tailored to learners' specific needs and levels (De La Vall & Araya, 2023). Second, AI tools demonstrate significant capability in providing real-time feedback (De La Vall & Araya, 2023; Qiao & Zhao, 2023) of various types, from pronunciation, cohesion, to lexical resources and grammar (Nguyen , 2024), helping learners improve their weaknesses and progress in their language learning (De La Vall & Araya, 2023; Nguyen, 2024). Third, most AI-based applications are widely accessible, user-friendly, and inexpensive, making it possible for learners, especially those with financial problems, to easily learn anywhere at any time (De La Vall & Araya, 2023). Fourth, interactive AI features drive engagement by offering relaxing and stimulating activities (Diverkar et al., 2021), keeping learners enthusiastic and motivated (De La Vall & Araya, 2023) to maintain regular practice and complete entire courses (De La Vall & Araya, 2023). Fifth, AI tools support self-regulated learning by helping learners set goals, plan tasks, manage time and monitor progress, all of which empower them to become more independent and active in their learning (Qiao & Zhao, 2023).

However, AI-powered language learning tools are not without limitations. Firstly, AI software relies on datasets for training; consequently, their outputs – while appearing authentic – often lack originality and creativity (Poole & Polio, 2023), and can occasionally be highly superficial and formulaic (Godwin-Jones, 2024). Secondly, since AI applications have no real-

life experience, they cannot empathize, understand and use language with the same social awareness as humans; consequently, their responses, though appearing objective and accurate, are generally erroneous and inappropriate (Godwin-Jones, 2024), lack consciousness and emotion (Giannakidou & Mari, 2024), and are thus inapplicable (Godwin-Jones, 2024). Thirdly, AI tools often lack cultural sensitivity, primarily reflecting Western, male-centered values (Cao et al., 2023; Godwin-Jones, 2024), leading to significant errors in diverse cultural contexts (De La Vall & Araya, 2023). Furthermore, AI's inability to accurately replicate idiomatic and colloquial nuances frequently results in awkward or erroneous phrasing (De La Vall & Araya, 2023). Fourthly, AI tools offer limited feedback capabilities, often providing less accurate error correction and less specific explanations than human instructors (De La Vall & Araya, 2023; Godwin-Jones, 2024). Fifthly, technical barriers – such as hardware incompatibility and software instability – frequently hinder the overall effectiveness of AI in language education (Alisoy & Sadiqzade, 2024).

2.3. Previous studies on AI-based language learning tools

Recent research has extensively explored various AI tools developed for language learning, with Large Language Models (LLMs) like ChatGPT and Gemini garnering significant attention. These tools were recognized for personalizing instructions, providing real-time feedback, and fostering low-anxiety environments that built learner confidence (Abas et al., 2023; Nguyen, 2024; Celik et al., 2025; Huanca et al., 2025; Songsiengchai, 2025; Tai & Chen, 2020). Specifically, Gemini's bilingual support and authentic scenarios effectively bridged the gap between structured practice and real-world application (Huanca et al., 2025; Nguyen, 2024), while Copilot offered unique multimodal engagement through voice-to-speech processing (Kovačić & Bubaš, 2024) and Google Assistant facilitated accessible environments for autonomous (Eragamreddy, 2025; Hadi & Junor, 2022) with interactive activities (Sharizan & Yulia, 2024) and individualized practice (Fathi et al., 2025). However, LLMs faced persistent challenges, including accuracy concerns, reliability issues, and limited server capacity (Abas et al., 2023). Comparative studies further indicated that ChatGPT was inferior to specialized tools like ELSA Speak for pronunciation feedback, or Gemini in analyzing learner strengths (Vu et al., 2025).

Beyond LLMs, specialized tools such as Google Assistant, Duolingo, and ELSA Speak offered distinct benefits for language development. Google Assistant and related chatbots were praised for increasing autonomy and reducing anxiety, though they struggled with non-native accents and hardware compatibility (Setiawan & Rauf, 2025). Similarly, gamified platforms like Duolingo and ELSA Speak enhanced vocabulary, grammar, and phonological accuracy through diverse learning materials and automated feedback mechanisms (Bahtiar et al., 2025; Darsih et al., 2021; Fitria et al., 2023; Widyasari & Maghfiroh, 2023). Nevertheless, Duolingo often lacked complex, multi-turn discourse whereas ELSA Speak's speech recognition could be compromised by ambient noise in non-controlled settings (Darsih et al., 2021; Khomariyah & Ekowijayanto, 2025).

Despite the growing popularity of these AI tools, their integration into self-regulated English speaking practice remains under-researched (Tuan, 2021). Existing literature has primarily focused on general self-learning or writing improvement (Thao et al., 2024), largely neglecting learner perceptions of AI as a specific assistant for independent speaking practice. This study addressed this scholarly gap by addressing the question " What are VAA AE students' perceptions regarding the benefits and limitations of using AI-based tools within a self-regulated speaking context?"

3. Methodology

The study employed a quantitative research method to investigate how VAA AE students perceived the benefits and limitations of AI-integrated self-regulated English speaking practice since quantitative surveys are the most effective way to provide an orderly and representative picture of student attitudes (Dörnyei, 2007). Data set comprised a questionnaire administered to 161 students specializing in AE at VAA. Prior to participation, all the students were provided with a consent form, which clearly outlined the study's purpose, methodology and expected research duration. Participation was entirely voluntary.

3.1. Setting and participants

This study was conducted at VAA, targeting AE students whose future careers demand high levels of communicative competence. Despite 18 credits of the 120-credit curriculum dedicated specifically to listening and speaking skills, a significant number of students struggle to reach the required communicative proficiency levels and increasingly turn to AI tools for self-practice. However, their actual experiences remain underexplored.

Participants were recruited using a convenience sampling method (Creswell & Poth, 2017). Online consent forms were distributed to 178 students currently enrolled in the AE program at VAA, of whom 175 agreed to participate. After excluding 14 students who lacked prior experience with AI tools, the final sample consisted of 161 participants.

3.2. Instruments

Data was collected via online questionnaires to explore VAA AE students' attitudes towards and experiences with AI-integrated English speaking self-practice. The instrument was developed based on a comprehensive literature review and underwent a pilot test with three English majors who were not the main study participants to ensure its comprehensibility and validity.

The final questionnaire comprised 29 items. The initial three questions addressed the participants' background experience with AI tools. The remaining 26 items were categorized into ten thematic groups based on the literature review, namely Personalization (Q4–Q5), Immediate feedback (Q6–Q7), Accessibility (Q8–Q10), Engagement (Q11–Q12), Self-regulated learning support (Q13–Q15), Data dependency (Q16–Q17), Illusory understanding (Q18–Q20), Cultural sensitivity (Q21–Q23), Feedback accuracy (Q24–Q26), and Technical issues (Q27–Q29).

3.3. Data collection and analysis

The questionnaire was distributed online to 175 AE students who volunteered to participate in the study and 175 completed questionnaires were returned, yielding a 100% response rate. However, only data obtained from 161 of these versions were analyzed. The 14 excluded questionnaires were from students who selected "No" to the first question that asked about their prior experience with AI tools for self-regulated English speaking practice.

The data collected were descriptively analyzed and the findings were presented as percentages, using SPSS version 20.

4. Results

4.1. Use of AI-based language learning tools for English speaking self-practice

Regarding the AI tools used, ChatGPT was the most popular with 64% of the students using it, followed by Duolingo and ELSA Speak, which were used by 47.2% and 34.8% of the

participants, respectively. Gemini and Copilot, with respective usage rates of 22.4% and 18.6%, ranked fourth and fifth. Google Assistant saw lower adoption at 11.2%. Call Annie, Speechling, TalkPal, Mondly, Andy, Poe, Cici, and Coach were used by fewer than seven students each and were consequently excluded from the final analysis.

In terms of usage duration, 61.5% of participants have practiced English with AI for over six months, while only 1.9% have used these tools for less than two months. The remaining students have between two and six months of experience. This widespread, long-term engagement ensures that the participants possess sufficient experience to provide valid reflective evaluations.

4.2. Perceived benefits of AI-based language learning tools

Table 1

Students' perceptions of AI tools' benefits

Benefits	Tools	ChatGPT	Copilot	Duolingo	Elsa Speak	Gemini	Google Assistant
	N	102	30	76	56	36	18
		Agree and Strongly agree (%)					
Personalization	Q4 – identifying improvement areas	86.3	93.3	84.2	73.2	88.9	94.4
	Q5 – customizing lessons	82.4	90	84.2	82.1	86.1	94.4
Immediate feedback	Q6 – offering real-time feedback	89.2	93.3	92.1	94.6	88.9	94.4
	Q7 – pinpointing errors	89.2	96.7	82.9	82.1	80.6	94.4
Accessibility	Q8 – accessible	91.2	90	96.1	94.6	88.9	100
	Q9 – user-friendly	90.2	83.3	89.5	89.3	83.3	94.4
	Q10 - affordable	79.4	80	81.6	75	75	83.3
Engagement	Q11 – offering stimulating activities	78.4	83.3	81.6	76.8	63.9	83.3
	Q12 – encouraging regular practice	79.4	73.3	82.9	80.4	72.2	88.9
Self-regulated learning support	Q13 – setting speaking goals	83.3	86.7	86.8	80.4	80.6	94.4

	Q14 – planning learning schedules	84.3	90	81.6	76.8	77.8	94.4
	Q15 – monitoring progress	93.1	96.7	92.1	91.1	94.4	94.4

The quantitative analysis revealed that AI tools were highly regarded for their pedagogical contributions, particularly in personalizing learning experience and providing immediate feedback. Google Assistant and Copilot emerged as the most effective for diagnostic support. An overwhelming 94.4% of Google Assistant users and 93.3% of Copilot users agreed that these tools accurately identified areas for improvement. Furthermore, Copilot led the category for pinpointing mistakes of various types with a 96.7% approval rating. While ChatGPT and Duolingo maintained high consistency, averaging between 82% and 89% across feedback metrics, ELSA Speak was the top-rated for providing real-time feedback with a 94.6% approval rating. ELSA Speak was, however, perceived as less effective at broad diagnostic identification at 73.2%.

Accessibility remained a primary strength of modern AI. Google Assistant achieved a perfect score of 100% for accessibility, followed closely by Duolingo and ELSA Speak, with respective agreement rates of 96.1% and 94.6%. Despite these high scores, the data suggested a fee barrier for certain tools; Google Assistant was rated as the most affordable at 83.3%, while ELSA Speak and Gemini were perceived as slightly less accessible in terms of cost at 75%.

Engagement levels remained consistent across the board. Google Assistant and Copilot both attained an 83.3% approval rating for offering engaging, relaxing, and stimulating activities. When encouraging regular practice, Google Assistant again led with an 88.9% agreement rate, demonstrating its effectiveness in maintaining student momentum. These results suggested that the gamified elements of tools like Duolingo and the interactive nature of AI assistants were critical to keeping students motivated outside of traditional classrooms.

AI tools also served as highly effective facilitators of self-regulated learning, providing students with the structure necessary to manage their own proficiency development. Copilot demonstrated exceptional utility in this area, with 96.7% of users reporting that the tool allowed them to monitor their progress effectively. Similarly, Google Assistant achieved a 94.4% agreement rate for its capacity to assist learners in both setting personal speaking goals and planning systematic learning schedules. These tools were obviously praised for their ability to bridge the gap between classroom instruction and autonomous practice.

4.3. Perceived limitations of AI-based language learning tools

Table 2

Students' perceptions of AI tools' limitations

	Tools	ChatGPT	Copilot	Duolingo	ELSA Speak	Gemini	Google Assistant
sLimitations	N	102	30	76	56	36	18
		Agree and Strongly agree (%)					

Data dependency	Q16 – lack of originality, creativity	63.7	73.3	68.4	60.7	50	72.2
	Q17 – superficial, formulaic responses	71.6	73.3	71.1	73.2	50	61.1
Illusory understanding	Q18 – erroneous, inappropriate responses	71.6	76.7	64.5	69.6	69.4	94.4
	Q19 – unconscious, unemotional reactions	65.7	60	65.8	71.4	66.7	83.3
	Q20 – contextually inapplicable responses	52.9	53.3	57.9	46.4	44.4	72.2
Cultural sensitivity	Q21 – lack of diversity	65.7	70	67.1	62.5	61.1	72.2
	Q22 – Western, male-centered cultural bias	54.9	66.7	52.6	48.2	52.8	55.6
	Q23 - unnatural idiomatic, colloquial phrasing	66.7	66.7	63.2	69.6	72.2	83.3
Feedback accuracy	Q24 – error identification failure	54.9	63.3	59.2	51.8	50	72.2
	Q25 – error correction failure	61.8	63.3	61.8	62.5	61.1	55.6
	Q26 – unspecific explanations	66.7	70	57.9	64.3	66.7	88.9
Technical issues	Q27 – compatibility problems	49	50	48.7	60.7	55.6	44.4
	Q28 – Internet problems	63.7	66.7	64.5	53.6	63.9	50
	29 – crashes, freezing	60.8	63.3	77.6	75	55.6	83.3

Despite the pedagogical benefits of AI, participants identified several functional and systemic limitations. Across all platforms, a significant number of students reported concerns regarding data reliance and superficiality. For example, 73.3% of Copilot users felt that the speaking examples generated by the tool lacked originality and creativity, and its responses tended to be formulaic and superficial.

Furthermore, the lack of real-world or emotional understanding remained a persistent issue. Google Assistant users expressed the highest level of concern in this area, with 94.4% reporting that the tool lacked conscious and emotional reactions when conversing with human users and occasionally generated erroneous, inappropriate, and thus inapplicable responses.

Regarding cultural and linguistic sensitivity, a majority of participants across all tools indicated that AI frequently struggled with the nuances of their native language. Specifically, 83.3% of Google Assistant users and 72.2% of Gemini users noted the tools' failure to accurately phrase Vietnamese idioms and colloquial expressions. This highlighted a clear gap in the cultural adaptability of current AI models.

Finally, feedback accuracy and technical stability were identified as major barriers to long-term adoption. While tools like ChatGPT and Copilot were noted for offering overly general explanations by approximately 67% to 70% of users, technical performance also flagged. Google Assistant and Duolingo experienced the most significant reliability issues during prolonged sessions, with respective 83.3% and 77.6% of their users reporting that the applications would crash or freeze during long interaction sessions, greatly demotivating them.

5. Discussion

The analysis above showed that all the six AI tools were positively assessed by AE majors, with each tool demonstrating particular strengths in helping them self-practice English speaking skills. Google Assistant consistently outperformed other tools in learning personalization, accessibility, affordability, and motivation. These findings corroborate existing literature, which identified Google Assistant as effective in providing stress-free (Tai & Chen, 2020), accessible environments for autonomous learning (Eragamreddy, 2025; Hadi & Junor, 2022) where speaking skills were fostered (Hadi & Junor, 2022) through interactive activities (Sharizan & Yulia, 2024) and individualized practice (Fathi et al., 2025). Copilot also received positive perceptions from AE students, standing out as a premier tool for pinpointing diverse linguistic errors, offering stimulating speaking activities, and enabling independent progress monitoring. These findings highlight Copilot's significant utility for speaking practice, contrasting with previous research that primarily focused on its role in writing improvement (Abdelrady et al., 2025; Esfandiari & Akbary, 2025). ELSA Speak received positive evaluations for providing real-time feedback, although students perceived it as less effective at pinpointing specific errors. These findings partially align with previous research on the tool's automated feedback mechanisms (Bahtiar et al., 2025; Darsih et al., 2021; Widyasari & Maghfiroh, 2023).

Beyond detailing the benefits of each investigated tool, the study also identified specific limitations hindering students from fully leveraging AI tools for self-regulated speaking practice. Notably, Google Assistant, though perceived as highly effective, was identified as the most problematic. Students reported a lack of originality, frequent generation of contextually inappropriate responses, and an inability to grasp Vietnamese colloquialisms. Furthermore, the tool often provided vague feedback and suffered from recurrent technical issues. These findings reveal drawbacks beyond those previously documented by Setiawan and Rauf (2025). Copilot, though perceived as effective in specific domains, also faced criticism for producing superficial, formulaic outputs and lacking robust error-correction capabilities. Furthermore, AE students noted a Western-centric bias in vocabulary suggestions and reported that its performance was heavily dependent on stable Internet connectivity. These findings contribute significantly to the field, as Copilot remains under-researched compared to more established AI counterparts. ELSA Speak also garnered some critiques regarding software compatibility.

This finding expands upon the drawbacks identified by Darsih et al. (2021), who previously characterized ELSA Speak's primary weaknesses as an ineffective audio response system.

While early literature (i.e. Abas et al., 2023) primarily championed ChatGPT as the benchmark for AI in education, the current research findings indicate that learners are increasingly diversifying their toolkits. The superior performance of Google Assistant and Copilot in pinpointing linguistic errors suggests that as students gain experience, they prioritize diagnostic precision over the conversational breadth of general models. This shift validates the argument by Vu et al. (2025) that general LLMs often lack the specific feedback mechanisms necessary for phonological and structural refinement. The findings also demonstrate that learners are essentially curating their own AI experience, moving toward specialized assistants that function as targeted diagnostic tools rather than mere conversational partners.

Another recurring theme in the literature – most notably in Tai and Chen (2020) – is the role of AI in lowering the affective filter, or the psychological barrier that hinders language production. The current study reinforces this, as most Google Assistant and Copilot users identified the tools as providing engaging and relaxing environments for practice. By removing the fear of judgment often present in human-to-human interactions, these tools promote a sense of psychological safety.

However, the findings regarding technical friction introduce a counter-narrative to the literature. While researchers often focus on the pedagogical success of these tools, the current study highlights that infrastructure reliability remains a significant hurdle. If an AI tool crashes during prolonged practice sessions, the psychological safety it creates is immediately replaced by demotivation.

The high approval ratings for self-regulated learning – specifically the high agreement rate on progress monitoring via Copilot – strongly support the theories of Eragamreddy (2025) concerning autonomous learning. The data shows that students are not just using these tools for passive input; they are actively using them to set goals and monitor their own growth. That means AI tools empower AE students to shift from passive recipients of instructions to active managers of their own learning process. This aligns with the broader academic consensus that the most successful AI-integrated learners are those who treat the technology as a strategic assistant rather than an automated teacher (Molenaar, 2022).

6. Conclusion

6.1. Conclusion

The current study addressed the research gap concerning AI-mediated, self-regulated speaking practice among AE majors. While general research on AI in language education is increasing, limited attention has been paid to specific perceptions of students using these tools for autonomous English speaking development.

The research findings revealed that participants generally held positive perceptions of AI tools as assistants. These tools were found to enhance learning motivation and engagement by providing personalized experiences, real-time feedback, and supportive environments for self-regulation. Furthermore, accessibility and affordability were identified as key drivers of user satisfaction. Among the investigated platforms, Google Assistant and Copilot emerged as the most effective regarding pedagogical benefits, whereas ChatGPT and Duolingo remained the most popular choices despite being less prominent in terms of specific performance scores.

However, the analysis also exposed significant barriers to effective self-learning. Participants reported a heavy dependence on training data, which resulted in a perceived lack

of real understanding and cultural sensitivity. These limitations often led to unnatural or inaccurate responses. Notably, although Google Assistant and Copilot were rated as highly effective, they were also identified as the most problematic due to frequent technical issues.

Ultimately, the study suggests that while AI tools are effective in enhancing speaking competence, tool selection must be strategically aligned with individual learner's objectives and preferences.

6.2. Recommendation

Based on this study's findings, AI tools are recommended for VAA AE students seeking to self-practice their English speaking skills. However, as no single AI tool is found to be flawless, learners are encouraged to select tools that match their own learning goals, needs and preferences. For instance, Google Assistant and Copilot are ideal for AE students who prioritize immediate feedback on weaknesses, detailed suggestions for improvement or a motivating and engaging learning environment. Google Assistant is also suitable for those who prefer personalized learning experiences and accessibility. Users of Google Assistant, however, should be mindful of the potential for inaccurate feedback, unnatural responses and technical issues during practice sessions. Users of Copilot must also remain vigilant regarding the tool's tendency toward superficiality and Western-centric bias. AI-generated content should be cross-referenced with various resources to ensure cultural and technical accuracy in an aviation context.

Strategic selection of AI tools allows AE students to develop high level of English speaking proficiency to meet the demanding requirements of the aviation sector.

6.3. Limitations and directions for future research

Due to time constraints, this research exclusively analyzed quantitative data collected via online questionnaires to explore students' perceived benefits and limitations of AI tools in self-regulated English speaking practice. Follow-up interviews were not conducted, preventing a deeper investigation into underlying issues, like reasons behind the popularity of ChatGPT and Duolingo despite their less prominent benefits, or why Google Assistant and Copilot, though perceived as highly effective, are not the most popularly used. In addition, participants were recruited through convenience sampling from a single institution, which may limit the generalizability of the findings to other Aviation English students and to the broader tertiary education context in Vietnam. The specific challenges associated with the use of individual AI tools were also beyond the scope of the present study. Future research should therefore consider adopting a mixed-methods design that combines quantitative and qualitative data to provide both broader patterns and deeper insights into students' use of AI tools for self-regulated English speaking practice. In particular, qualitative interviews could help clarify the reasons behind disparities between the perceived effectiveness and popularity of specific tools, as well as explore learners' experiences, preferences, and difficulties in using individual AI tools. Expanding the sample to include students from multiple institutions would also help improve the generalizability of the findings and provide a more comprehensive understanding of AI-assisted language learning in the Vietnamese tertiary context.

Bionote

Nguyễn Thị Nguyệt Ánh is a seasoned English language educator with over 30 years of teaching experience. She currently serves as a lecturer at the Vietnam Aviation Academy, where she contributes to the development of English curricula. Her primary research interests lie in the field of English language teaching, with a dedicated focus on the enhancement of language skills and pronunciation. Throughout her extensive career, she has remained committed to exploring innovative pedagogical approaches that bridge the gap between classroom theory and real-world application. This study reflects her ongoing commitment to improving communicative competence in tertiary education.

Nguyễn Thị Ngọc Quý is an undergraduate student at the Vietnam Aviation Academy, majoring in English language studies. Driven by a lifelong passion for the English language, she chose this major to deepen her linguistic expertise within a specialized technical context. Alongside her studies, she has developed a keen interest in scientific research, focusing on the intersection of language acquisition and real-life communication. This paper represents her initial foray into scholarly inquiry, reflecting her commitment to contributing to the field of Applied Linguistics. Her research aims to bridge the gap between academic theory and practical language application for future aviation professionals.

#67 LEVERAGING GENERATIVE AI TO ADDRESS VIETNAMESE EFL LEARNERS' CHALLENGES IN ENGLISH LITERATURE: A CLOSE READING AND RUBRIC-BASED ASSESSMENT FRAMEWORK FOR THIRD-YEAR UNIVERSITY STUDENTS

Nguyễn Thị Thư Hiên[1]

Abstract

This study identifies the challenges faced by third-year Vietnamese EFL learners in an English Literature course and evaluates an eight-stage ChatGPT-assisted close reading framework designed to address these challenges. Drawing on a needs analysis and a pilot study with 122 third-year English majors at HUFLIT using selected passages from Charlotte Brontë's *Jane Eyre*, the study found three major areas of difficulty: linguistic complexity, cultural unfamiliarity, and procedural uncertainty in literary analysis. These challenges appear to arise not merely from general English proficiency limitations, but from the specific linguistic, cultural, and analytical demands of literary study. The proposed framework operationalizes Vygotsky's Zone of Proximal Development by alternating AI-supported activities, such as vocabulary and contextual inquiry, literary device identification, and AI-assisted reflection, with AI-free tasks that preserve independent reading, analysis, discussion, revision, and rubric-based self-evaluation. The results indicate generally favorable learner perceptions: 88.5% of participants reported increased confidence, and mean scores on all post-pilot questionnaire items exceeded 4.00. Nevertheless, because of the exploratory nature of the research and the use of descriptive statistics as well as learners' perceptions collected at one Vietnamese university, the framework should be interpreted as an exploratory, evidence-informed pedagogical model rather than statistically confirmed evidence of improvement in learning. Replication is recommended before broader implementation in other regional EFL contexts.

Keywords: Generative AI in EFL education, literature instruction, close reading, rubric-based assessment, Vietnamese tertiary EFL

1. Introduction

1.1 Background of the Study

English literature courses are an integral component of university-level English language programmes. However, studying English literary works can be difficult for third-year students of B2 and C1 levels of English language proficiency. This difficulty is partly associated with the shift from textual comprehension to more complex forms of literary interpretation and analysis. Previous research on the challenges faced by EFL students in Vietnam has confirmed that reading and analyzing English literature texts can be problematic due to the use of sophisticated literary devices and the long nature of canonized literary texts (Nguyen, 2023).

1.2 Statement of the Problem

[1] *Ho Chi Minh City University of Foreign Languages – Information Technology; Email hienntt@huflit.edu.vn*

Several issues in learning EFL literature have been highlighted in the literature. Firstly, due to the complexity of the literary texts, language learners may experience linguistic problems in studying literary texts as a result of complex vocabulary, stylistics and syntax of these texts (Paran, 2008). Secondly, due to lack of necessary knowledge about the cultures associated with literary texts, understanding and interpreting these texts become harder for learners (Brantmeier, 2005). Thirdly, EFL learners accustomed to reading texts for information sake may face significant challenges in engaging with the aesthetic analysis of the literary texts (Rosenblatt, 1994). In sum, learners may feel uncertain about how literary analysis should be structured and evaluated, making the rubric-based assessment crucial (Panadero & Jonsson, 2013).

1.3 Research Objectives

The aim of this study is:

_ to examine challenges experienced by third-year Vietnamese EFL students while studying English literature;

_ to develop a ChatGPT-assisted framework intended to support Vietnamese EFL students in studying English literature;

_ to assess Vietnamese EFL students' attitudes toward using this framework.

1.4 Significance of the Study

It can be argued that the implementation of Generative AI, especially ChatGPT, in EFL literary analysis may help overcome these difficulties. By using Vygotsky's (1978) concept of Zone of Proximal Development as a theoretical base, some recent works in the field have suggested that Generative AI may provide scaffolding to learners by supporting their efforts during the writing process with immediate formative feedback and instructions (Xiao et al., 2025). Although Vietnamese EFL students already use AI-powered tools during their writing tasks, some learners still lack proper guidance in applying these tools successfully (Nguyen et al., 2025). Generative AI in language education is a widely researched topic, but only a few publications focus specifically on foreign language literary learning - an important area of language education that has long been discussed in the pedagogical literature (Law, 2024; Paran, 2008). Therefore, this study seeks to fill the gaps by exploring Generative AI in foreign language literary learning and suggesting classroom implications.

What distinguishes the present study from the broader body of AI-assisted EFL research is its domain-specific design. Unlike general AI-assisted EFL writing frameworks that focus on composition tasks with unrestricted AI access (e.g., Xiao et al., 2025; Teng, 2024), the present framework targets a largely neglected intersection: the close reading of canonical literary texts within a structured, alternating AI/AI-free instructional sequence. Specifically, AI interaction is constrained to three pedagogically defined steps (Steps 2, 3, and 7), directly operationalising Vygotsky's (1978) ZPD scaffolding in literary-rather than general writing-contexts. Furthermore, the five-criterion analytical writing rubric developed for this study is designed specifically for EFL literary analysis tasks, as opposed to the general writing rubrics used in most AI-EFL studies. Taken together, these features represent a domain-specific contribution that existing AI-EFL frameworks have not previously addressed empirically.

1.5 Research Questions

To reach the mentioned objectives, the research is focused on the following research questions:

1. What challenges do third-year Vietnamese EFL students experience during English literature studies?

2. How do third-year Vietnamese EFL students perceive the role of the ChatGPT-integrated framework in supporting their literary analysis tasks?

3. What are third-year Vietnamese EFL students' attitudes toward the proposed framework in terms of helpfulness, confidence, and engagement?

1.6 Scope and Limitations

The current study includes third-year undergraduate English majors at HUFLIT, where *Jane Eyre* by Charlotte Brontë served as the primary literary text for the pilot implementation. The framework developed in this study was designed to support students in close reading and rubric-based literary analysis through controlled, teacher-guided use of ChatGPT. Several boundaries should be noted. Firstly, the research involved just one institutional sample made up of 122 learners, making its applicability to any other situation outside that setting rather restricted. Secondly, only descriptive statistics were used for analysis, without the application of inferential statistical methods; therefore, the observed differences between survey mean scores should be interpreted descriptively rather than as statistical evidence of learning gains. Thirdly, learners' attitudes were collected through self-report measures, which may have influenced their responses. Fourthly, the rapid development of generative AI technologies means that the findings may require future re-examination as AI tools and classroom practices continue to evolve.

1.7 Organization of the Study

This paper is organized as follows. The review of relevant literature on EFL literary instruction, rubric-based assessment, Generative AI, and close reading will be presented in Chapter 2. In Chapter 3, the methodology of the study is outlined, covering the procedures of needs analysis and pilot experiment design. Chapter 4 discusses the findings. Chapter 5 contains conclusions of the research.

2. Literature Review

The present review addresses four interconnected themes that inform the design of the proposed framework: challenges in EFL literary instruction, close reading pedagogy in L2 contexts, rubric-based formative assessment, and the use of Generative AI in EFL education. While the pedagogical foundations of the framework draw on established scholarship in literary pedagogy and formative assessment, these are situated within an evolving body of recent empirical research on AI-mediated language learning, reflecting the dual theoretical and technological grounding of the study.

2.1 Issues of EFL Literary Instruction

Literature has long been recognised as a valuable resource in EFL education, contributing to learners' linguistic, cultural, and cognitive development (Paran, 2008). However, a persistent gap exists between the intended purposes of literary instruction and the actual experiences of L2 learners. Paran (2008), drawing on an international survey of EFL practitioners, identifies an enduring tension in foreign language education between language teaching objectives and the demands of literary study - a tension that stems partly from unexamined assumptions about learners' interpretive readiness.

Many Vietnamese students studying the English language face similar difficulties when interacting with canonical literature due to its complex nature. As noted by Lazar (1993) and

Paran (2008), literary works include archaic language, highly complex constructions, and literary stylistics, which cannot be easily mastered within communicative language teaching. Culturally, the historical and social contexts embedded in literary works - particularly those from the Victorian era - present interpretive barriers for learners whose own cultural frames of reference differ substantially from those of the texts (Lazar, 1993; Brantmeier, 2005). Analytically, the transition from information-focused reading to interpretive engagement with aesthetic and symbolic dimensions of text poses a distinct pedagogical challenge (Rosenblatt, 1994) - one documented empirically among Vietnamese final-year English majors by Nguyen (2023). These three difficulty areas directly informed the needs analysis design of the present study.

2.2 Close Textual Analysis in L2 Learning Contexts

While close reading forms an integral part of literary studies, its role in second-language instructional contexts remains relatively underexplored. In this respect, it becomes necessary to draw upon Rosenblatt's (1994) transactional theory, according to which reading can be defined as an interactive process during which cultural and linguistic backgrounds of the reader affect text comprehension. Lazar (1993) develops this position practically, proposing classroom activities that facilitate learners' access to literary and cultural meaning- several of which correspond to the AI-supported contextual inquiry incorporated in Steps 2 and 3 of the present framework. Paran (2008) further supports the integration of language development objectives within literary instruction, arguing that close attention to textual language need not be subordinated to thematic or analytical goals. Together, these perspectives provide the pedagogical rationale for a close reading sequence that interleaves AI-supported language and device analysis with independent interpretive tasks, as operationalised in the eight-step framework described in Section 3.

2.3 Rubric-based Assessment in L2 Literary Writing

A further challenge in EFL literary instruction concerns assessment transparency. Panadero and Jonsson (2013), in a systematic review of rubric use in educational settings, find that rubrics support learning by making success criteria explicit, thereby enabling learners to engage in more effective self-assessment and self-regulation. This is especially significant in literary writing tasks, where learners may perceive interpretive performance as inherently subjective and therefore difficult to evaluate against fixed criteria. Black and Wiliam (1998), in their foundational synthesis of formative assessment research, similarly demonstrate that clearly communicated performance criteria enhance learner engagement and metacognitive control - effects that extend to affective dimensions of learning. In L2 contexts, this affective dimension carries particular weight: Horwitz et al. (1986) identify fear of negative evaluation as a central component of foreign language anxiety, suggesting that explicit rubric criteria may not only clarify expectations but also reduce anxiety associated with literary performance tasks. It is on this basis that rubric-based self-assessment was incorporated as Step 8 of the present framework, using five criteria designed specifically for EFL literary analysis.

2.4 Generative AI in EFL Education

The integration of Generative AI into EFL instruction has expanded rapidly since the public release of ChatGPT, prompting a growing body of empirical and review-based research directly relevant to the design of the present framework. In their scoping review of ChatGPT use in EFL writing instruction, Xiao et al. (2025) identify scaffolding within Vygotsky’s (1978) Zone of Proximal Development as a key pedagogical mechanism through which AI can support language learners, while also noting that scaffolding should be gradually reduced to prevent

over-dependence on AI-generated output. Teng (2024) extends this analysis, acknowledging the benefits of AI-assisted feedback and idea generation while highlighting risks of academic integrity violations and passive reliance on AI responses - concerns that informed the decision to restrict AI interaction to three defined steps in the present framework.

Recent research similarly suggests that AI is most pedagogically valuable when embedded within structured instructional design and accompanied by explicit teacher guidance rather than used as a standalone tool. Kohnke et al. (2023) further argue that the ethical and effective use of AI in education depends on the development of digital competencies, including the ability to critically evaluate AI-generated outputs. Similarly, Kostka and Toncelli (2023) claim that the educational potential of using ChatGPT in English language teaching becomes possible only with clear instructional guidance. Empirical studies of AI-assisted writing further support this position: Song and Song (2023) and Yan (2023) find that ChatGPT can support writing improvement, motivation, and reflection, but only under conditions of structured implementation rather than unguided use. In the Vietnamese EFL context specifically, Nguyen et al. (2025) report that while students are already active users of AI tools, they lack the pedagogical frameworks necessary to apply them effectively in academic tasks - a finding that directly motivates the teacher-designed prompt templates used in Steps 2, 3, and 7 of the present study. Woo et al. (2025) further demonstrate that explicit instruction in prompt formulation is a necessary condition for productive AI-mediated learning, providing additional support for the controlled prompting approach adopted here. Taken together, these studies establish that the pedagogical value of AI in EFL settings is contingent on structured design, teacher guidance, and learner accountability - principles that underpin the present framework's alternating AI/AI-free architecture.

Relatedly, the capacity for critical AI literacy - defined as the selective, evaluative engagement with AI-generated output rather than passive acceptance - has emerged as an important learning objective in its own right (Long & Magerko, 2020), and one that is explicitly developed through the accept/reject reflection task in Step 7.

2.5 Research Gap

To summarize, the literature review presented above highlights several aspects of EFL literary instruction, such as the difficulties of working with literary texts, the importance of structured close reading, learning advantages associated with rubrics, and the circumstances under which AI scaffolding fosters student autonomy. However, relatively little empirical work has examined how these components can be integrated within a single pedagogical framework for Vietnamese EFL literary instruction. More precisely, the novelty of the present study lies in three interlocking design features that, to the authors' knowledge, have not been combined in prior empirical work. First, AI assistance is structurally constrained to three task-specific steps using teacher-designed prompt templates, differentiating this framework from studies in which learners engage with AI freely and without pedagogical scaffolding. Second, the analytical writing rubric is calibrated specifically for EFL literary analysis, addressing five criteria - device identification, analysis of effect, author's intention, textual engagement, and analytical language - rather than the general writing criteria commonly assessed in AI-EFL writing research. Finally, the framework is designed specifically for literary texts, where linguistic, cultural, and interpretive demands require forms of scaffolding that differ from those typically reported in AI-assisted EFL writing studies.

3. Methodology

3.1 Research Design

For the purpose of this study, an exploratory mixed-methods design was adopted, combining quantitative survey data with qualitative analysis of open-ended responses. This design is suitable for applied linguistics research because it allows numerical patterns from survey data to be interpreted alongside learners' written responses (Dörnyei, 2007). In this study, the needs analysis survey informed the framework design, while the post-pilot survey evaluated learners' perceptions after implementation.

3.2 Participants and Setting

Third-year students studying English Literature as one of their modules made up the subjects of the current study. Purposeful sampling technique was employed to sample subjects who were currently undergoing the English Literature program (Dörnyei, 2007). Based on programme requirements, participants were expected to have achieved B2–C1 levels of English proficiency. This research study was carried out in one institution to ensure consistent instructional settings throughout the investigation. The consent of the participants was sought before data collection since the researcher assured them that their participation in the study will not affect their final grades. Participation in this study was completely voluntary. There were a total of 122 third-year undergraduate students enrolled in this study through the need-analysis survey, framework piloting, and post-pilot evaluation survey.

3.3 Instruments

Two paper-based surveys were designed and used by the researcher to collect data. Paper-based surveys were selected since they facilitated easier classroom implementation and consistency.

Survey 1 (Needs Analysis Survey) was distributed prior to implementing the ChatGPT-assisted close reading instruction framework. The questions focused on gathering both quantitative and qualitative data related to linguistic, cultural, and analytical difficulties learners encountered in their literary studies, experiences in performing a close reading, and their attitude towards Generative AI technologies. Data were collected using Likert scale items and open-ended questions.

Survey 2 (Post-Pilot Feedback Survey) was conducted after implementing the instructional framework and aimed at investigating the usefulness of the framework for the learners' literary learning. The question structure of both surveys enabled comparisons of learners' experiences and perceptions prior to and after implementing the ChatGPT-assisted instruction framework.

3.4 Procedures

This study involves the following five phases of investigation. The first phase involved the administration of needs analysis survey to find out what difficulties learners encounter during their EFL literary learning. Phase 2 entailed the development of the ChatGPT-assisted instruction framework with an eight-step close reading procedure and a five-criteria analytical writing rubric based on the theoretical perspectives explained above. The current ChatGPT-assisted instruction framework comprises eight sequentially ordered steps involving alternations between AI-assisted and AI-free steps. It enables learners to perform close reading gradually, thereby implementing the theory behind Vygotsky's (1978) Zone of Proximal Development. The table below provides an overview, the primary focus and AI status of each step of the current framework.

Table 1

The Eight-Step ChatGPT-Assisted Instructional Framework Overview

Step	Activity	Focus	AI status
1	First reading	Initial comprehension; personal response	AI-free
2	Vocabulary and context inquiry	Archaic language; cultural and historical background	AI-assisted
3	Literary device identification	Identifying and labelling target devices in the passage	AI-assisted
4	Independent analytical writing	First-draft paragraph; independent literary analysis	AI-free
5	Peer discussion	Sharing and critiquing analytical responses	AI-free
6	Revised independent writing	Redrafting paragraph based on peer feedback	AI-free
7	AI-assisted reflection	Evaluating and responding to ChatGPT-generated feedback	AI-assisted
8	Final synthesis and self-evaluation	Summative paragraph with rubric-based self-assessment	AI-free

Note. Steps 2, 3, and 7 entail teacher-designed prompt templates in order to facilitate specific learning purposes through AI interaction. Remaining steps do not incorporate AI support to promote independent literary analysis. Detailed instructions for classroom implementation can be found in Appendix A. Appendix B presents the analytical writing rubric.

Phase 3 of this study involved the piloting of ChatGPT-integrated close reading framework among third-year undergraduate students undertaking an English Literature course. During the pilot process, multiple passages of Charlotte Brontë's *Jane Eyre* (1847) containing extracts from Jane's staying at Thornfield Hall and the garden scene were used. Close reading activities were carried out individually and in pairs. AI interaction was integrated in some phases using teacher-created prompts while others remained explicitly AI-free. In phase 4, a post-pilot evaluation survey was distributed to students in order to find out how useful the implemented framework was. The last phase involved data analysis and results reporting.

3.5 Data Analysis

Likert-scale data collected from the two surveys were analyzed descriptively using means, standard deviations, frequencies, and percentages. In addition, conceptually related items across the two surveys were compared descriptively to examine whether the post-pilot usefulness ratings corresponded to the difficulty areas identified in the needs analysis. These comparisons between surveys did not serve as inferential pre-test post-tests since Survey 1 measured perceived difficulty while Survey 2 assessed perceived usefulness and confidence after piloting. Open-ended answers were analyzed using thematic analysis to determine recurring patterns in relation to linguistic challenges, cultural unfamiliarity, task understanding, learner confidence, and critical assessment of feedback from the AI tool.

4. Results and Discussion

This chapter outlines the results obtained through implementation of the framework. Section 4.1 reports the needs analysis survey results addressing Research Question 1: challenges experienced by third-year Vietnamese EFL undergraduate students in studying literature. Section 4.2 discusses the findings of the post-pilot evaluation for Research Questions 2 and 3 regarding the usefulness of the ChatGPT-enabled close reading approach, the function of the rubric used, and the level of engagement among students.

4.1 Needs Analysis Findings

4.1.1 Participants' profile

Phase 1 involved a total number of 122 participants who were all third-year undergraduates taking the English literature course at HUFLIT. As can be seen from Table 2 below, the majority (n=103, 84.4%) of the learners have reached level B2 (Upper-intermediate) while others were at C1 level (n=19, 15.6%). This complies with the standards established by the English program regarding language proficiency level. When asked about their experience with literary courses, 75.4% of the learners described it as "difficult" or "very difficult" while none rated it as "easy".

Table 2

Participants' Profile (N = 122)

Characteristic	**n**	**%**
Proficiency Level		
B2 (Upper-Intermediate)	103	84.4
C1 (Advanced)	19	15.6
Overall Experience with Literature Courses		
Very difficult	36	29.5
Difficult	56	45.9
Neutral	21	17.2
Manageable	9	7.4
Easy	0	0.0

4.1.2 Self-reported difficulties: survey 1, section B

In Table 3 presented below are the means of the six Likert items used to assess learners' experience in dealing with three different types of difficulties in literary analysis of English language texts: linguistic complexity (B1, B6), lack of familiarity with cultural background (B2), and problems in performing analytic tasks (B3, B4, B5).

Table 3

Summary statistics for survey 1, section B: perceived difficulties (N = 122)

Item	**M**	**SD**	**Category**
B1. Archaic vocabulary & complex sentence structures	4.31	0.72	Linguistic
B2. Cultural references (historical events, social norms)	4.18	0.81	Cultural
B3. Identifying literary devices (e.g., metaphor, symbolism, irony)	4.09	0.88	Text Analysis
B4. Approaching close reading tasks systematically	4.23	0.76	Text Analysis
B5. Uncertainty about assessment criteria	4.05	0.91	Text Analysis
B6. Writing analytical responses in English	3.97	0.95	Linguistic

Note. Items rated on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree). M = Mean; SD = Standard Deviation.

Given the high mean value of 4.31 and low standard deviation of SD=0.72, item B1 ("Archaic vocabulary & complex sentence structures") can be regarded as the one where students report the highest level of difficulty in comprehension of literary texts. This finding

confirms Paran's (2008) statement that literary texts can pose linguistic demands higher than those of communication. The low standard deviation suggests consistent response patterns.

Coming second was the cultural challenge (item B2): M=4.18; SD=0.81. The qualitative data collected during this study also showed that many students report experiencing problems connected with cultural differences between themselves and the cultures depicted in literary works. For example, one student found that it was hard for her to understand “why characters behave the way they do” in Victorian novels. Another student mentions that she struggles to comprehend “religious and class structures in old English society”. These results confirm the findings of Lazar (1993) and Brantmeier (2005) regarding the difficulties related to cultural issues experienced by L2 readers in literary reading activities, as well as the importance of prior knowledge/background schema to comprehension.

The mean scores for all three items in Text Analysis category (B3, B4 and B5) were high at 4.05 to 4.23. Thus, lack of clarity regarding the procedure of conducting a close reading and literary analysis can be regarded as the next major difficulty area. Given that the mean value of item B4 ("Approaching close reading tasks systematically"; M=4.23, SD=0.76) was slightly higher than the mean of item B3 ("Identifying literary devices"; M=4.09, SD=0.88), it can be concluded that in addition to difficulties in understanding literary techniques, it is hard for the students to follow a systematic procedure. This was further confirmed by results obtained in Section C of the questionnaire (item C1): only 31.7% of respondents stated that they were aware of close reading techniques. These findings are consistent with the distinction established by Rosenblatt (1994) between informative and interpretive reading, as well as Nguyen’s (2023) conclusion about the challenge caused by literary devices. Finally, the high mean of item B5 (assessment uncertainty; M=4.05, SD=0.91) suggests another potential problem - unclear assessment expectations. This idea is consistent with Panadero and Jonsson’s (2013) discussion of the importance of transparency in formative assessment criteria.

To summarize, the results of needs analysis offer compelling evidence for three main difficulty areas discussed in literature - linguistic, cultural, and procedural. The last is specifically connected with text analysis techniques.

4.1.3 Prior AI use and attitudes toward Generative AI

The results gathered in Section D of Survey 1 indicate that the respondents' level of prior experience with artificial intelligence varies. Most participants (84.4%) have tried to use various AI products including ChatGPT at least once before. Out of these, 13.1% reported using AI regularly, 40.2% - sometimes, while 31.1% tried AI just once or twice. At the same time, 15.6% of the respondents indicated that they had never used any artificial intelligence applications. Among all the respondents who previously engaged in such activity (n=103), the main reasons why they employed AI were the translation of challenging parts (92.2%), searching for cultural or historical background (89.3%), developing ideas for analysis (88.3%), and understanding literary devices (86.4%) whereas receiving feedback on writing proficiency was rare (only 45.6%).

Table 4

AI tools usage experience and Generative AI attitude: survey 1, section D (N = 122)

Item / Category		
Prior AI Use (D1)	**n**	**%**
Yes, regularly	16	13.1

Yes, sometimes	49	40.2
Tried once or twice	38	31.1
Never	19	15.6
Prior Uses of AI, if applicable (D2 - select all that apply)	**n**	**%**
Translating difficult passages	95	92.2
Understanding cultural/historical context	92	89.3
Brainstorming ideas for analysis	91	88.3
Getting explanations of literary devices	89	86.4
Getting feedback on my writing	47	45.6
Attitudes Toward ChatGPT (Likert Scale, D3-D5)	**M**	**SD**
D3. ChatGPT can help me understand difficult texts	3.81	0.94
D4. I can rely on ChatGPT's explanations for academic purposes	3.12	1.03
D5. Comfortable using ChatGPT if guided by teacher	4.27	0.68

Note. Percentages for D1 are calculated from the total sample (N = 122). For D2, percentage scores are obtained from learners who had prior exposure to AI (n = 103; the 19 learners without prior experience of AI were excluded). The learners had more than one response option in their answers, and therefore, the total percentage may exceed 100%. Items in D3-D5 have been assessed based on a five-point scale (where 1 is 'strongly disagree' and 5 is 'strongly agree').

Responses for attitudes toward ChatGPT vary depending on its purpose. While item D5 (willingness to use ChatGPT if guided by the teacher) received the highest mean value (M=4.27, SD=0.68), indicating the high willingness of students to engage in AI-assisted activities under the guidance of a teacher, D4 (trusting AI-generated explanations) received the lowest score (M=3.12, SD=1.03), indicating that learners' opinions on trusting AI are quite divided. Open-ended responses given in answer to question D6 showed similar concerns about becoming overly reliant on AI technologies, as well as possible ethical issues, which is consistent with the discussion in Teng (2024) on the challenges connected with using ChatGPT in writing EFL.

4.2 Post-Pilot Evaluation Findings

4.2.1 Framework usefulness: survey 2, section E

Following the piloting of the ChatGPT-based close reading and rubric assessment, the survey was administered again to the same sample of respondents (N=122). The items and results of Section E, which evaluates the usefulness of the framework, as well as item F2 and F3 from Section F, are provided in Table 5 below. Items' mean scores were high above 4.00 (the threshold for positive evaluation) in all cases.

Table 5

Post-pilot survey 2: Framework usefulness and confidence ratings (N = 122)

Item	**M**	**SD**
Section E: Framework Usefulness		
E1. ChatGPT helped me understand vocabulary & language	4.42	0.61

Item	M	SD
Section E: Framework Usefulness		
E2. ChatGPT helped me understand cultural/historical context	4.36	0.67
E3. ChatGPT-assisted close reading improved my text analysis	4.28	0.73
E4. The rubric clearly explained assessment criteria	4.51	0.58
E5. The rubric helped me realize my strengths & weaknesses	4.33	0.64
E6. AI-integrated lessons more helpful than traditional lessons	4.17	0.82
Section F: Confidence & Peer Recommendation		
F2. More confident in close reading tasks after framework	4.38	0.69
F3. Would recommend this course format to other students	4.45	0.62

Note. Items rated on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree). M = Mean; SD = Standard Deviation.

Among the framework-usefulness items in Section E, the highest mean score was recorded for item E4. This finding aligns with that gathered during the needs analysis, where the difficulty connected with assessing literature was also mentioned (item B5, M=4.05). The high average score of item E4 following the pilot session is consistent with Panadero & Jonsson's (2013) finding that rubrics promote self-evaluation and clarify expectations to facilitate learning, and aligns with Black & Wiliam's (1998) broader formative assessment principle that making success criteria explicit supports the development of learners' metacognitive strategies of performance control. The learners supported this view, highlighting the value of the rubric for clear expectation setting. For example, one of the respondents mentioned that it was "like a map" for him. Another participant described the rubric as a checklist. Items E1 and E2, which concern using ChatGPT for assistance in vocabulary comprehension (M=4.42) and studying the cultural background (M=4.36), were positively evaluated by the participants. Qualitative responses to these items revealed that using ChatGPT to ask follow-up questions and get explanations based on their language competence (ZPD) was also helpful for the participants. Consistent with the findings of Xiao et al. (2025) on scaffolded learning within ZPD, learners mentioned such benefits in their qualitative responses. Here are some sample responses to the open-ended question F4 ("What was the most valuable part of AI-integrated close reading for you?").

"I like the step-by-step process. It helps me understand difficult text more easy. ChatGPT also explain vocabulary and culture background clearly."

"The AI feedback was useful because I can see my mistakes quickly. It also gives me ideas when I do not know where to begin my analysis."

These responses suggest that students valued not only the step-by-step structure but also the immediate feedback provided by ChatGPT when working through literary analysis tasks.

Finally, item E3 (ChatGPT-assisted close reading improved my text analysis; M = 4.28, SD = 0.73) also received a positive rating. Since this item concerns close reading, the result suggests that learners perceived the eight-step procedure as beneficial to their analytical work. However, because the study did not include objective pre- and post-performance measures, this finding should be interpreted as perceived analytical support rather than confirmed improvement in literary competence. This interpretation is consistent with Xiao et al.'s (2025)

discussion of gradually reduced AI scaffolding as a way to support learner independence while limiting over-reliance on AI output.

A cross-survey descriptive comparison was conducted to examine whether the areas of difficulty identified in the needs analysis corresponded to the areas in which learners later perceived the framework as useful. The comparison was not intended as an inferential pre-post test, since Survey 1 measured perceived difficulty whereas Survey 2 measured perceived usefulness after the pilot. Instead, the surveys were used to explore the alignment between learners' identified needs and their perceptions of the framework's usefulness. One of the most strongly reported difficulties in Survey 1 was archaic vocabulary and complex sentence structures (B1: M = 4.31, SD = 0.72). This corresponded to a high usefulness rating for ChatGPT-based language explanations following the pilot study (E1: M = 4.42, SD = 0.61). Similarly, cultural references were identified as another major area of difficulty (B2: M = 4.18, SD = 0.81), while AI-supported explanations of cultural and historical context were also rated highly after the pilot (E2: M = 4.36, SD = 0.67). Finally, procedural difficulties in close reading were also prominent in the needs analysis (B4: M = 4.23, SD = 0.76), and ChatGPT-guided close reading received a similarly positive post-pilot rating (E3: M = 4.28, SD = 0.73). These descriptive patterns suggest that the framework was aligned with the main difficulty areas identified before implementation. However, because the paired items were designed to assess related but non-identical constructs, such comparisons should not be viewed as quantitative evidence of learning gains but rather as descriptive evidence of instructional alignment.

4.2.2 Activity preferences and confidence: survey 2, sections F and G

The results obtained in answering to item F1 of Section F are presented in Table 6 below. Respondents were required to choose the two most helpful activities from those offered within the framework (out of five options). The highest percentage of respondents chose guided close reading tasks with AI prompts (n=73, 59.8%). The second most popular task among them was conducting research on the cultural/historical context via ChatGPT (n=55; 45.1%), followed by self-assessment according to the rubric before submission (n=52; 42.6%). The task that was chosen least frequently was peer discussion following any AI-related tasks (n=22; 18.0%).

Table 6

Most Useful Framework Activities: Survey 2, Item F1 (N=122; up to 2 selections)

Activity (F1 - select up to 2)	**n**	**%**
Guided close reading tasks with AI prompts	73	59.8
Using ChatGPT to research cultural/historical context	55	45.1
Rubric-based self-assessment prior to submission	52	42.6
Using ChatGPT to explore vocabulary and language	42	34.4
Peer discussions after AI-related activities	22	18.0

Note. Percentages reflect the proportion of respondents selecting each activity and may exceed 100% as participants could choose up to two options.

The least chosen activity following an AI-related activity was that of having a discussion among peers (n=22; 18.0%). This suggests that participants did not regard peer discussion as one of the most valuable components of the framework. However, quantitative results need to be considered in connection with the results obtained through open-ended questions. Even though participants did not name discussion among peers as one of the

activities they like, some respondents noted that they enjoyed participating in such discussions, especially because the learning process included the social component. For example, one learner suggests *"maybe give more time for discussion and writing".* Another learner mentions that *"the framework should have shorter reading passages first. Some parts of Jane Eyre are still difficult and long for me to follow."* These improvement suggestions indicate that while participants valued the AI-assisted components of the framework most highly, the low selection rate for peer discussion points to a need for redesigning or better scaffolding Step 5 in future implementations to make its value more apparent to learners. Items F2 and F3 also received high mean scores, indicating generally positive learner attitudes toward the framework. Furthermore, these findings are also supported by categorical responses in Section G (post-pilot confidence in literary analysis). 88.5% of the participants said they were "much more confident" (40.2%) or "somewhat more confident" (48.4%) in approaching close reading after the application of the framework. None of them felt less confident.

Table 7

Post-Pilot Confidence in Close Reading: Survey 2, Item G1 (N=122)

Confidence Level (G1)	**n**	**%**
Much more confident	49	40.2
Somewhat more confident	59	48.4
No change	14	11.5
Less confident	0	0.0

Note. Percentages may not sum to 100 due to rounding.

From the open-ended responses to item G2, it becomes apparent that many learners consider their increased confidence in literary analysis as due to the decrease in *"reading anxiety"* and the step-by-step procedure introduced in the framework. Indeed, as one of the respondents notes, *"Having a step-by-step process helped make it (literary analysis) from overwhelming to manageable".* Responses to F6 provide evidence that in addition to overcoming reading anxiety, the students feel more confident when approaching literature classes and are more willing to discuss the text in class. For example, one respondent said that *"before (using the framework), I think literature was very difficult and stressful. But after these lessons, I feel more confident and more interested because I know how to read and analyze better now."* Another participant notes that after using the framework, he *"doesn't feel literature is only for very good students. Now I feel more comfortable asking questions and sharing my opinion about the text".*

However, 11.5% of the learners responded they experienced no change in confidence after piloting the framework. From their written feedback, this might be because some of them already possessed high levels of confidence or because the framework was tested in a relatively short timeframe.

4.2.3 Critical AI literacy and independent analysis

One interesting finding related to Step 7, during which learners critically analyzed and accepted/rejected ChatGPT suggestions based on writing justifications for their choices, is that the activity was initially difficult but later seen as positive by most participants. Out of the 122 participants who responded to the post-pilot questionnaire, 74 (60.7%) mentioned Step 7 in their free responses. Most participants noted the difficulty of the activity in its initial stages

followed by benefits they obtained from analyzing their choices of accepting or rejecting ChatGPT's suggestion. This result corroborates Nguyen et al.'s (2025) view on the importance of providing clear instruction in AI-assisted EFL studies and may contribute to alleviating over-reliance on AI-related tools observed by Teng (2024).

To further develop the analysis of the open-ended responses, Table 8 presents selected representative examples that provide insight into how the participants perceived the framework in terms of several significant aspects. These examples were chosen because they exhibit recurring patterns in the qualitative data, including linguistic and cultural support, procedural clarity, formative feedback, independent analysis, critical evaluation of AI output, and learner confidence.

Table 8

Representative Qualitative Evidence from Open-Ended Responses (Selected Examples)

Theme	**Representative open-ended response**	**Interpretation**	**Framework link**
Linguistic and cultural access	"It helps me understand difficult text more easy. ChatGPT also explain vocabulary and culture background clearly."	AI support appeared to make difficult literary language and cultural background more accessible.	Step 2
Procedural clarity	"I like the step-by-step process."	The staged sequence helped reduce uncertainty about how to approach close reading.	Steps 1-8
Formative feedback	"The AI feedback was useful because I can see my mistakes quickly."	AI feedback helped learners notice weaknesses in their analysis or writing.	Step 7
Idea generation for analysis	"It also gives me ideas when I do not know where to begin my analysis."	AI functioned as an initial scaffold for developing analytical direction, not as a replacement for final independent writing.	Step 7
Rubric clarity	"It was like a map/checklist."	The rubric made expectations visible and supported self-assessment.	Step 8
Confidence	"Having a step-by-step process helped make it (literary analysis) from overwhelming to manageable."	The framework appeared to reduce anxiety and increase confidence in literary analysis.	Steps 1-8
Cultural understanding	"I understand better why the characters acted that way after learning about Victorian society."	AI-supported contextual inquiry helped learners connect literary events with historical and cultural background knowledge.	Step 2
Independent analysis	"At first I wanted ChatGPT to give me the answer, but later I tried writing my own ideas first."	The framework encouraged learners to maintain independent analytical thinking before consulting AI support.	Steps 4-6
Critical evaluation of AI feedback	"I did not agree with all ChatGPT suggestions because some ideas did not match my interpretation of the text."	Learners demonstrated selective acceptance of AI-generated feedback rather than passive dependence.	Step 7
Learner engagement	"The activities made literature lessons more interesting because	The structured sequence appeared to increase engagement and reduce	Steps 1-8

	I could explore the text step by step."	feelings of being overwhelmed by literary texts.	

A closer reading of these qualitative excerpts helps explain how the framework addressed learners' linguistic, cultural, and procedural difficulties beyond the descriptive survey results. The response about vocabulary and cultural background suggests that Step 2 helped learners access difficult language and contextual information that might otherwise prevent meaningful engagement with the literary text. The grammatical inaccuracies in the quoted response, such as "more easy" and "ChatGPT also explain," are retained as part of the learner's original wording; they also remind readers that perceived literary engagement occurred even while English production was still developing. Procedurally, the repeated reference to the "step-by-step process" indicates that the value of the framework came not only from AI explanations but also from the sequencing of AI-assisted and AI-free tasks. Comments on AI feedback suggest that Step 7 functioned as formative support by helping learners notice mistakes and generate possible analytical directions. Importantly, responses related to independent analysis and selective acceptance of ChatGPT suggestions indicate that learners did not simply rely on AI output passively. Instead, the structured sequence appeared to guide them toward using AI as a scaffold while preserving their own interpretive judgment in the AI-free stages.

4.3 Summary

The findings show convergence between the quantitative and qualitative data across the three research questions. Needs analysis highlighted three interrelated challenges - linguistic, cultural, and procedural - which were used in designing the framework (RQ1). In relation to RQ2, post-pilot results showed that learners perceived the eight-step approach and rubric as helpful for their literary analysis assignments. Finally, high mean scores for each item assessing usefulness of the framework, along with increased confidence and lessened reading/assessment anxiety indicate positive affective responses to the framework among participants (RQ3).

5. Conclusion

5.1 Summary of Findings

This study examined the difficulties experienced by third-year Vietnamese EFL students studying English literature and developed, implemented, and evaluated a ChatGPT-integrated pedagogical framework designed to address these challenges. Based on needs analysis data collected from 122 students enrolled in HUFLIT and the implementation of the framework using excerpts from *Jane Eyre* by Charlotte Brontë, the findings address the three research questions.

First, with regard to the identification of challenges, three categories of difficulties emerged through the needs analysis, which included linguistic challenges, cultural differences, and procedural challenges in close reading and literary analysis. Such challenges align with findings from earlier research on EFL literary instruction (Paran, 2008; Lazar, 1993; Rosenblatt, 1994) and were consistently reflected in the participants' responses.

Second, as to the design of the eight-step ChatGPT-integrated pedagogical framework, the proposed framework enabled the participants to engage in literary analysis tasks by alternating between several AI-supported activities, such as vocabulary glossing, inquiry regarding cultural context, and formative feedback for literary analysis drafts, and non-AI-supported activities, in which learners performed close reading tasks independently. The designed alternation can be considered the practical manifestation of the concept of the Zone

of Proximal Development (Vygotsky, 1978). Furthermore, the rubric consisting of five criteria addressed the issue of assessment uncertainty detected in the needs analysis and demonstrated the application of Black and Wiliam's (1998) framework.

Third, in relation to affective reactions toward the pilot framework implementation, the participants displayed generally positive affective responses toward it. Most students reported increased confidence regarding close reading, with 88.5% stating that they became more confident due to the pilot implementation of the proposed framework. The responses also suggested a perceived reduction in reading and assessment anxiety among the participants. In addition, the element of artificial intelligence literacy in Step 7 was initially perceived as a difficult one; however, learners later came to evaluate it more positively, which suggests a perceived contribution to learners' critical engagement with AI feedback.

5.2 Theoretical and Pedagogical Contributions

The findings of the present study make two significant contributions. Theoretically, it applies Vygotsky's (1978) notion of the Zone of Proximal Development and Rosenblatt's (1994) transactional theory to the context of teaching EFL literature using AI technology. This study also demonstrates an application of Black and Wiliam's (1998) ideas regarding the function of transparent assessment criteria within the framework of formative assessment in EFL literary learning. Pedagogically, the study provides a concrete eight-step framework incorporating classroom procedures, AI-supported activities, teacher-designed prompt templates, and analytical rubrics, which aims to support learners in addressing the three major categories of difficulty consistently identified among the Vietnamese EFL literature learners. In contrast to many proposals for integrating AI into EFL learning, the current study's framework has been developed specifically for close reading of literary works, thus addressing the particular needs of the learners in the field.

5.3 Limitations and Directions for Future Research

This study is subject to several limitations. First, it was conducted through one pilot implementation with a single institutional sample, which limits the generalizability of the findings. Further studies incorporating several groups of participants from various institutions would provide stronger evidence regarding the educational value of the proposed framework. Second, the experiment was performed only at HUFLIT, so the results can be influenced by the institutional practices of this particular educational organization. Third, statistical analyses, such as paired-samples t-tests or Wilcoxon signed-rank tests, were not used; hence, the results cannot be regarded as statistically verified evidence of improved language skills of the students. Fourth, the experiment measured only attitudes and perceptions of the participants and not their performance based on pre- and post-pilot writing scores. Lastly, the fact that excerpts from *Jane Eyre* were used for teaching purposes may restrict the applicability of the results obtained for other novels. Further investigation into the application of the framework is needed. Replication studies across multiple Vietnamese and regional EFL contexts are needed to assess the external validity of the framework and to determine whether its classroom value extends beyond the present setting. Future studies should also retain individual-level response data and incorporate inferential statistical analyses, such as paired-samples t-tests or Wilcoxon signed-rank tests, together with objective performance measures such as pre- and post-pilot writing scores. Such designs would make it possible to examine not only learners' perceptions of usefulness, but also measurable changes in literary analysis and analytical writing performance. Further research may also investigate learners' long-term development of critical AI literacy and teachers' perceptions of implementing and sustaining the framework.

5.4 Implications

The findings of the present study have implications for three stakeholder groups in Vietnamese higher EFL education. It should be noted, however, that given the single-institution scope of the study and the absence of inferential statistical testing, the following implications should be treated as preliminary and evidence-informed rather than conclusive. First, the study provides an evidence-informed classroom framework that can be implemented easily by teachers of English literature with no need for technical background. Furthermore, the prompts and rubrics were designed for adaptation to other literary texts and contexts. Second, the findings of the needs analysis can assist curriculum designers and programme coordinators in reconsidering the structure of literature courses, incorporating close reading, AI scaffolding, and formative rubric-based assessment as structured components of literature courses. Third, this study shows policy makers in Vietnam and the wider region that AI technologies may be integrated into existing EFL programs in pedagogically structured ways that are intended to support, rather than replace, independent analytical work in literary learning; however, broader adoption should be informed by replications across diverse institutional contexts.

Since English literature courses will likely retain their place in Vietnamese higher EFL education in the future, this study suggests that Generative AI, embedded in a pedagogically structured framework, might alleviate the difficulties experienced by students during English literature study.

Biographical Note

Nguyen Thi Thu Hien is a lecturer at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). She earned her M.A. in Applied Linguistics from La Trobe University, Australia, in 2005. Her research interests centre on applied linguistics, TESOL, and classroom discourse. Hiên is also a translator. She has co-translated *Coaching Salespeople into Sales Champions* by Keith Rosen (Thanh Niên Publishing House, 2023). Email: hienntt@huflit.edu.vn.

QUESTIONNAIRES

SURVEY 1 - NEEDS ANALYSIS

This questionnaire is part of a research study examining Vietnamese EFL students' challenges in English Literature and their attitudes toward ChatGPT-assisted close reading. Your participation is voluntary and anonymous. The information collected will be used solely for academic research purposes. Please answer all questions honestly based on your current knowledge and experience. There are no right or wrong answers. The questionnaire should take approximately 10-15 minutes to complete.

Thank you for your valuable contribution to this research.

Section A: Learner Background

A1. How proficient are you in English at the moment (self-assessed)?

☐ B1 (intermediate)
☐ B2 (upper intermediate)
☐ C1 (advanced)
☐ C2 (proficient)

A2. How would you describe your experience with English literature courses?

☐ very difficult
☐ difficult
☐ neutral
☐ manageable
☐ easy

Section B: Difficulties with Literature

Please mark your level of agreement to the following statements (**1 = strongly disagree; 2 = disagree; 3 = neutral; 4 = agree; 5 = strongly agree)**

Statement	**1**	**2**	**3**	**4**	**5**
B1. Archaisms and complicated structure of sentences in literary texts cause many problems for me.	☐	☐	☐	☐	☐
B2. It is hard for me to understand the cultural context of English literature (references to historical events, social practices).	☐	☐	☐	☐	☐
B3. I find it difficult to identify literary devices (e.g., metaphor, symbolism, irony) in texts.	☐	☐	☐	☐	☐
B4. I do not know how to conduct a close reading.	☐	☐	☐	☐	☐
B5. I have doubts about what is expected from me in literary analysis tasks.	☐	☐	☐	☐	☐
B6. Analytical writing in English causes some difficulties for me.	☐	☐	☐	☐	☐

B7. What makes studying English literature especially hard for you? Please explain briefly.

Answer: …….

Section C: Experience with Close Reading & Assessment

Please rate your agreement with the following statements (**1 = strongly disagree; 2 = disagree; 3 = neutral; 4 = agree; 5 = strongly agree)**

Statement	**1**	**2**	**3**	**4**	**5**
C1. I understand the meaning of close reading and the way it should be done.	☐	☐	☐	☐	☐

C2. The rubric/assessment criteria provided by my teacher helps me understand how to improve my work.	☐	☐	☐	☐	☐
C3. I get sufficient feedback on my literary analysis tasks.	☐	☐	☐	☐	☐

C4. What kind of support or guidance would help you most in close reading tasks?
Answer: …….

Section D: Attitudes Toward Generative AI

D1. Have you used ChatGPT or other similar applications in studying English literature so far?

☐ Yes, regularly
☐ Yes, sometimes.
☐ Once or twice.
☐ Never before.

D2. If yes, for what purposes? (Select all that apply)

☐ Translating difficult passages
☐ Understanding cultural/historical context
☐ Getting explanations of literary devices
☐ Getting feedback on my writing
☐ Brainstorming analysis ideas
☐ Other: _____

Please rate your agreement with the following statements (**1 = strongly disagree; 2 = disagree; 3 = neutral; 4 = agree; 5 = strongly agree)**

Statement	**1**	**2**	**3**	**4**	**5**
D3. I think ChatGPT can help me understand difficult literary texts.	☐	☐	☐	☐	☐
D4. I can rely on explanations and analysis provided by ChatGPT for academic purposes.	☐	☐	☐	☐	☐
D5. I would feel comfortable using ChatGPT for studying literature with my teacher's guidance.	☐	☐	☐	☐	☐

D6. What concerns, if any, do you have about using AI tools in your literature studies?
Answer: …….

SURVEY 2

POST-PILOT FEEDBACK

This questionnaire is part of a research study examining your perception of the ChatGPT-integrated close reading and rubric-based assessment framework you have just completed. Your participation is voluntary and anonymous. The information collected will be used solely for academic research purposes. Please answer all questions honestly based on your experience with the framework. There are no right or wrong answers. The questionnaire should take approximately 10-15 minutes to complete.

Thank you for your valuable contribution to this research.

Section E: Framework Usefulness

Please indicate the degree of your agreement to the following statements (**1 = strongly disagree; 2 = disagree; 3 = neutral; 4 = agree; 5 = strongly agree)**

Statement	**1**	**2**	**3**	**4**	**5**
E1. ChatGPT integration improved my understanding of difficult vocabulary and language in literary texts.	☐	☐	☐	☐	☐
E2. ChatGPT improved my comprehension of the cultural and historical context of the texts.	☐	☐	☐	☐	☐

E3. ChatGPT-assisted close reading practice helped me enhance my abilities to analyze literary texts.	☐	☐	☐	☐	☐
E4. The rubric introduced in this course made it clearer what was expected from me in my analysis.	☐	☐	☐	☐	☐
E5. The rubric helped me realize my strengths and weaknesses in literary analysis.	☐	☐	☐	☐	☐
E6. Compared to the traditional lessons, AI-integrated lessons were more helpful for me in studying literature.	☐	☐	☐	☐	☐

Section F: Learners' Experience

F1. What activity was the most helpful for you in this course? Choose no more than two.

☐ Exploring vocabulary and language with ChatGPT
☐ Using ChatGPT to research cultural/historical context
☐ Guided close reading tasks with AI prompts
☐ Rubric-based self-assessment prior to submission
☐ Peer discussions after AI-related activities

Please indicate the degree of your agreement to the following statements (**1 = strongly disagree; 2 = disagree; 3 = neutral; 4 = agree; 5 = strongly agree)**

Statement	**1**	**2**	**3**	**4**	**5**
F2. I felt more confident approaching close reading tasks after using the AI-integrated framework.	☐	☐	☐	☐	☐
F3. I would recommend this course format to other students studying literature.	☐	☐	☐	☐	☐

F4. What was the most valuable part of AI-integrated close reading for you?

Answer: ……

F5. What should be added or improved about the framework? Please be specific.

Answer: ……

F6. What changes occurred in your attitude to studying English and American literature after these lessons?

Answer: ……

Section G: Overall Reflection

G1. After completing these lessons, how would you rate your confidence in conducting close reading literary texts?

☐ much more confident
☐ somewhat more confident
☐ no change
☐ less confident

G2. Is there anything else you would like to share about your experience with AI-supported literature learning?

Answer: ……

Appendix A

Note: The prompt templates and samples given in this appendix are representative examples taken from just one class using the garden scene (Chapter 23). During the pilot implementation, several passages of Jane Eyre were used.

Classroom Implementation

The next section describes the steps that both the teacher and the students should take during the pilot in the EFL literature class.

Context Setting

Text: from *Jane Eyre* (during her stay at Thornfield Hall)
AI tool: ChatGPT (used only in Steps 2, 3, and 7)
Class format: individual/paired

8-Step Procedure

Step 1: First reading (individual/ no AI)

Teacher does	Students do
✓ Assigns a passage (Ch. 23-Jane and Rochester in the garden in Thornfield) ✓ Tells students: *"Read silently. Don't look anything up now."* ✓ Teacher may show an image of a Victorian era manor house	✓ Read the passage for comprehension, underlining words/sentences that puzzle ✓ Answer in 2-3 sentences: *"What do I understand so far? What puzzles me?"*

Step 2: AI-assisted vocabulary & context (individual/ AI allowed)

Teacher does	Students do
✓ Hand out a prompt template that was pre-made, such as the following: *"I am an EFL student reading Jane Eyre (1847). Please define for me the following words/phrases and provide cultural/historical background, when appropriate: (word list)"* ✓ Ensure students use ONLY the template	✓ Use prompt template to paste words to ChatGPT ✓ Note down definitions/contexts in personal vocabulary log ✓ NOTHING ELSE. No asking ChatGPT for summary or analysis now

Step 3: AI-assisted literary device identification (paired/ AI allowed)

Teacher does	Students do
✓ Hand out another prompt template, such as: "This is a passage from *Jane Eyre*. Can you tell me whether there are literary devices and, if so, briefly explain their effect? (paste passage) ✓ Conduct a short class-wide discussion, such as: "What devices did ChatGPT find?" "Do any pairs feel the AI misidentified literary devices here? Why do you say so?" "What device stands out to you most in this passage – and why?"	✓ Work in pairs to submit the passage to ChatGPT ✓ Compare the AI's findings against your first observations in Step 1 ✓ Highlight literary devices in your copy of the text

Step 4: Independent analysis (individual/ no AI)

Teacher does	Students do

✓ Collect phones/laptops or move to the 'AI free zone' ✓ Hand out writing prompt such as the following: *"Please choose ONE literary device found in the previous step. Now, in your own words, explain why Brontë used it and its effect."* (This is an important assessment point; the teacher observes student thinking.)	✓ Write a paragraph about it independently (**no AI or partner**) ✓ The purpose is to generate **learning data** about their independent capacity

Step 5: Peer discussion (paired/ small group/no AI)

Teacher does	**Students do**
✓ Conduct structured pair-share: *"Now share your paragraph with your partner. Do you agree?"*	✓ Read each other's paragraphs from Step 4 ✓ Give feedback verbally to each other - *"I think Brontë used this device because…"* - *"My partner identified…which I didn't notice…"* etc. ✓ Identify 1 thing you'd like to improve

Step 6: Revised independent writing (individual/ no AI)

Teacher does	**Students do**
✓ Allow time for students to revise their Step 4 paragraph in light of peer feedback ✓ Explain that THIS is their work now; it shows progress.	✓ Now write a new version independently ✓ **The difference** between Step 4 and Step 6 **IS** the outcome

Step 7: AI-assisted reflection & extension (individual/ AI allowed)

Teacher does	**Students do**
✓ **Hand out another template prompt:** *"This is the draft of my analysis paragraph about Jane Eyre. Can you help me improve my paragraph? Specifically, (a) suggest a way to strengthen my argument and (b) another topic I can investigate."*	✓ Paste your Step 6 paragraph to ChatGPT ✓ Get suggestions from ChatGPT and reflect in writing about whether you agree - What did the AI say? - Do I agree? - Will I use it?

Step 8: Final synthesis (individual/ no AI)

Teacher does	**Students do**
✓ Assign an end-of-unit essay/journal writing prompt (to be done independently) Example: *"Discuss how Brontë uses imagery and symbolism to reveal Jane's emotions. In particular, describe the effect of these literary devices used together on Jane's views on love and identity."*	✓ Do the assignment: • Write the final paragraph independently (no AI) • Apply the rubric to self-assess your paragraph before submission, scoring each of the five criteria and writing one sentence to justify each score • Propose one revision idea for any criterion where your score is low

Key roles of teachers during the pilot procedure

- Gatekeeper: ensures only certain steps include AI
- Prompt designer: makes sure prompts to ChatGPT are academically appropriate
- Observer: Steps 4&6 provide insight into unassisted student thinking

- Facilitator: conducts Step 5 so that students critically examine AI's output

PROMPT for step 2: List of difficult vocabulary words and phrases

I am a university EFL student in Vietnam reading *Jane Eyre* by Charlotte Brontë (published 1847). I am currently studying an excerpt describing Jane and Rochester in the garden at Thornfield Hall.

Please help me with the following words and phrases I found difficult while reading. For each item:

1. Give a simple English definition (avoid advanced vocabulary)
2. Explain the historical or cultural context from Victorian England if relevant
3. Give one short example sentence showing how the word is used

Here are my words/phrases:

e.g.: *convulsively, impetuous, vehemence, mastery, petrified, communion, reverence, anguish.*

REMEMBER:

✓ Paste only your word list into the slot at the bottom

✓ Write down the explanations in your vocabulary log by hand

✓ Ask ChatGPT again if an explanation is unclear

✗ Do NOT ask ChatGPT to summarize the plot

✗ Do NOT ask ChatGPT to analyze characters or themes

✗ Do NOT change the prompt - use the template as written

PROMPT for step 3: Identifying Literary Devices in a Passage

I am a university EFL student in Vietnam. My partner and I are doing a close reading of a passage from *Jane Eyre* by Charlotte Brontë.

Please read the passage below and help us identify literary devices. We have already studied these five devices in class: imagery, foreshadowing, symbolism, flashback, and irony.

For each device you find in the passage:

1. Name the device (only from the five listed above)
2. Quote the exact words or phrase from the passage where it appears
3. Explain in 2-3 simple sentences what effect it creates for the reader

If a device from the list does not appear in the passage, do not invent one - just skip it.

The passage:

"Jane, do you hear that nightingale singing in the wood? Listen!" In listening, I sobbed convulsively; for I could repress what I endured no longer; I was obliged to yield, and I was shaken from head to foot with acute distress. When I did speak, it was only to express an impetuous wish that I had never been born, or never come to Thornfield.

"Because you are sorry to leave it?"

The vehemence of emotion, stirred by grief and love within me, was claiming mastery, and struggling for full sway, and asserting a right to predominate, to overcome, to live, rise, and reign at last: yes, - and to speak.

"I grieve to leave Thornfield: I love Thornfield: - I love it, because I have lived in it a full and delightful life, - momentarily at least. I have not been trampled on. I have not been petrified. I have not been buried with inferior minds, and excluded from every glimpse of communion with what is bright and energetic and high. I have talked, face to face, with what I reverence, with what I delight in, - with an original, a vigorous, an expanded mind. I have known you, Mr. Rochester; and it strikes me with terror and

anguish to feel I absolutely must be torn from you for ever. I see the necessity of departure; and it is like looking on the necessity of death."

Important:

Only identify devices within this specific passage.

Do NOT give us any overall plot summary, character analysis, or thematic essay.

AFTER YOU RECEIVE THE OUTPUT, WHAT TO DO

✓ Compare AI results with your own Step 1 observations - what did you miss? What did the AI miss?

✓ Highlight and annotate your printed passage for each device found

✓ If you disagree with the AI, note your reason - your interpretation is valid

✗ Do NOT copy the AI's explanation word-for-word into your annotation

✗ Do NOT ask the AI to write a full analysis paragraph. That is Step 4, done alone.

PROMPT for step 7: Receiving Feedback on Analysis

I am a university EFL student in Vietnam. I have just written an analysis paragraph about a passage from *Jane Eyre* by Charlotte Brontë as part of a close reading assignment.

Please read my paragraph below and give me feedback in two parts only:

Part 1: Strengthen my argument

Suggest ONE specific way I can make my analysis stronger. Focus on how well I explain the effect of the literary device on the reader. Do not rewrite my paragraph for me - just give me a clear suggestion.

Part 2: Extend my thinking

Suggest ONE related theme or critical perspective from Jane Eyre that connects to what I have written. For example: gender and independence, social class, the Gothic tradition, or Jane's moral growth. Explain briefly why it is relevant to my paragraph.

Important: Do NOT rewrite my paragraph or give me a model answer. I want suggestions I can think about and decide whether to use myself.

My paragraph:

"In this passage, Brontë use imagery to show Jane's strong emotion when she have to leave Thornfield Hall. When Jane say she was "shaken from head to foot with acute distress," the reader can imagine how much pain she feel in her body. This physical imagery help us understand that Jane's sadness is not just in her mind but also in her whole body. Brontë also use the image of the nightingale singing in the wood at the beginning of the passage. This create a contrast between the beauty of nature outside and the suffering of Jane inside. Overall, the imagery in this passage make the reader feel sympathy for Jane and show that she is a woman with very deep feeling."

Another example:

"Brontë use symbolism in this passage to express Jane's feeling about her relationship with Mr. Rochester. The nightingale at the beginning of the passage is a symbol of love and sadness in Victorian literature. Rochester ask Jane to listen to the nightingale just before she tell him her true feeling, so this symbol it suggest that their love is beautiful but also painful. Another symbol is "the necessity of death" which Jane use to describe leaving Thornfield. Death here does not mean real death but it symbolise the end of something very important in Jane's life. These two symbols show that Brontë want the reader to understand that Jane's love for Rochester and for Thornfield is very deep and it cannot be easily forget."

AFTER YOU RECEIVE FEEDBACK, REFLECT IN WRITING

✓ Write: 'The AI suggested... I agree/disagree because...'

✓ Decide for yourself whether to use the suggestion in Step 8

✓ Compare AI feedback with your peer's feedback from Step 5 - any overlap?
✗ Do NOT ask the AI to rewrite your paragraph
✗ Do NOT use the theme from Part 2 without understanding why it connects

Appendix B

Analytical Writing Rubric for Close Reading Paragraph

This rubric is applied to evaluate the paragraph of analytical writing completed by students in Step 8 of the eight-step close reading process. This rubric includes five criteria that are rated using a four-level scale (0.5, 1, 1.5, and 2). The highest possible score a student can receive for this assignment is 10 points. Following formative assessment guidelines outlined in Section 2.3, this rubric makes explicit the evaluation criteria in order to facilitate self-assessment before submission.

Criterion	2 - Excellent	1.5 - Proficient	1 - Developing	0.5 - Beginning
C1. Device identification	Correct identification of the literary device; precise quotation from the text.	Correct identification; relevant quotation from the text with minor imprecision.	Literary device identified but not accurately quoted; paraphrasing occurs.	Literary device incorrect or not identified.
C2. Analysis of effect	Concise and precise description of the effects of the literary device on the reader.	Reader's effect is explained but vaguely described without specifics.	Reader's effect is briefly mentioned but not explained in detail.	No explanation of effect of device on reader; only retelling occurs.
C3. Author's intentions	Explains why the author used this device; relates to characters and themes.	Connection between the literary device and character or theme present.	Mention of the author's intentions with some imprecision (e.g. "Brontë wants to show...").	No mention of the author's intentions and the use of the device.
C4. Engagement with the text	Good engagement with specific words or phrases used by the author.	Broad engagement with quotation but focusing on its general meaning.	Presence of quotation without engagement with specific language used.	No quotation and lack of engagement with the quotation.
C5. Analytical language and coherence	Use of precise analytical language ("conveys," "implies"); logical paragraph.	For the most part coherent and clear; some imprecise language.	Frequent use of informal language, imprecise wording, and weak paragraph structure.	Paragraph lacks coherence; imprecision prevents comprehension.

Scoring guide

Each of the five criteria is assessed separately on the scale below:

Score	Level	Score	Level
2	Excellent	1	Developing
1.5	Proficient	0.5	Beginning

Grading scale (out of 10 points)

Total score	Grade
9-10	Distinction

7-8.5	Credit
5-6.5	Pass
Under 5	Needs support

Self-evaluation instructions (Step 8)
Prior to submitting your paragraph for grading, do the following:

1. Read your paragraph according to all five criteria.
2. Assess yourself in relation to each of these criteria (score of 0.5, 1, 1.5, or 2).
3. Write down one sentence explaining your score for each criterion.
4. Propose one revision idea per criterion in case of low scores.

#71 INTEGRATING CLASSDOJO INTO WARM-UP ACTIVITIES TO SUPPORT EFL LEARNERS' WRITING PERFORMANCE AT A VIETNAMESE LANGUAGE CENTER

Chi Nguyen[1], Tran Le Khanh Phuong[2]

Abstract

This study investigates the integration of ClassDojo into warm-up activities as a form of pedagogical support for EFL writing instruction in a Vietnamese language center. Rather than functioning as a direct instructional tool, ClassDojo was embedded in the pre-writing stage to enhance learners' engagement, readiness, and motivation prior to writing tasks. A quasi-experimental mixed-methods design was employed with KET-level learners at Nam Do Language Center. Data were collected through writing tests, a student questionnaire, and semi-structured interviews.

The results indicated that the experimental group demonstrated greater improvement in writing performance than the control group. This improvement was observed at the immediate post-test and was maintained at the delayed post-test, suggesting more stable short-term retention. In addition, learners reported generally positive perceptions of the ClassDojo-supported warm-up activities, particularly in terms of perceived ease of use, perceived usefulness, engagement and readiness, and motivation.

The findings suggest that ClassDojo can support writing development indirectly by enhancing the conditions under which writing occurs. The study provides practical implications for integrating simple gamified tools into the pre-writing phase to improve learner engagement and readiness in EFL writing instruction.

***Keywords**:* ClassDojo, warm-up activities, EFL writing, learner engagement, gamification

1. Introduction

Writing is widely recognized as a core skill in English as a Foreign Language (EFL) education due to its central role in academic assessment and communication(Hyland, 2003; Weigle, 2002). However, it remains one of the most challenging skills for learners, as it requires the coordination of multiple cognitive and linguistic processes, including idea generation, organization, and language accuracy (Flower & Hayes, 1981). In addition, affective factors such as anxiety and low confidence may reduce learners' willingness to engage in writing tasks (Akhtar et al., 2019; Rasool et al., 2023). As a result, writing performance is influenced not only by linguistic competence but also by learners' readiness and engagement prior to task execution.

Within this perspective, warm-up or pre-writing activities play an important role in preparing learners for writing. These activities help activate prior knowledge, recall vocabulary, and reduce anxiety before learners begin writing tasks (Yuk & Yunus, 2021).

[1]*HUFLIT University*
[2] *Graduate student, HUFLIT University*

Despite their potential, warm-up stages are often minimized in practice, particularly in time-constrained instructional settings, resulting in limited support for learners' readiness.

At the same time, gamification has been increasingly applied to enhance engagement in language learning. By integrating elements such as points, rewards, and feedback, gamification can increase learner participation and motivation (X. Li et al., 2022; Zhang & Hasim, 2023). In writing instruction, however, gamification is generally considered an indirect support mechanism, influencing engagement and readiness rather than directly improving writing skills (Wang, 2023).

One widely used gamified platform is ClassDojo, which provides real-time feedback and reward systems to reinforce learner participation (Corser et al., 2025). While ClassDojo has been commonly used for classroom management and engagement, it has rarely been examined as a pedagogical tool integrated into specific instructional stages. In particular, its role within warm-up activities as a pre-writing support mechanism remains underexplored.

This gap is particularly relevant in Vietnamese EFL contexts, where learners often face difficulties in writing due to both linguistic limitations and low motivation (Nguyen, 2021; Whitty et al., 2022). In private language centers, where instructional time is limited and maintaining engagement is essential, the need for effective pre-writing support becomes more pronounced. Although digital tools are widely adopted, their use has largely focused on classroom management rather than writing preparation (Phan, 2024).

Addressing this gap, the present study investigates the integration of ClassDojo into warm-up activities in EFL writing lessons at a Vietnamese language center. Rather than positioning ClassDojo as a direct instructional tool for teaching writing, the study conceptualizes it as an indirect pedagogical support embedded within the pre-writing stage. Through features such as points, feedback, and visual rewards, ClassDojo is expected to enhance learners' engagement, readiness, and motivation before writing tasks, which may in turn be associated with improvements in writing performance.

Importantly, this study does not assume a direct causal relationship between the use of ClassDojo and writing outcomes. Instead, writing performance is interpreted as a context-dependent result shaped by multiple factors, including learner engagement and readiness. In addition to examining immediate performance outcomes, the study also considers whether such improvements are sustained over time, thereby providing a more comprehensive understanding of instructional impact.

The study is guided by the following research questions:

1. To what extent does the integration of ClassDojo into warm-up activities affect EFL learners' writing performance?

2. What are learners' perceptions of using ClassDojo in warm-up activities to support their writing performance?

By focusing on both performance outcomes and learner perceptions, this study contributes to the literature by situating gamification within the pre-writing stage of instruction. The findings are expected to provide practical implications for integrating gamified tools into warm-up activities, particularly in EFL contexts where enhancing learner readiness and engagement is a key instructional concern.

2. Literature Review

2.1 Writing Performance in EFL Contexts

Writing performance in EFL contexts is commonly defined as learners' observable written output produced under specific task conditions and evaluated using explicit criteria (Weigle, 2002; Shaw & Weir, 2007). Unlike writing ability, which reflects underlying competence, writing performance is context-bound and measurable, making it suitable for empirical investigation.

In standardized frameworks such as those of Cambridge Assessment English, writing performance is typically assessed across dimensions including content, organization, and language use (Cambridge University Press & Assessment, 2024). This multidimensional approach enhances reliability and allows for criterion-referenced evaluation. However, performance is not solely determined by linguistic competence. It reflects the interaction between learners' knowledge, task demands, and contextual conditions (Hyland, 2003; Weigle, 2002).

Importantly, recent studies emphasize that writing performance is also influenced by pre-task conditions, including learners' engagement and readiness (Fleckenstein et al., 2024; Zenouzagh et al., 2025). Therefore, improvements in writing outcomes should be interpreted as context-dependent rather than direct results of a single instructional intervention. In this study, writing performance is examined both in terms of immediate outcomes and potential sustained effects over time.

2.2 Cognitive and Affective Demands in EFL Writing

Writing is widely recognized as a cognitively demanding activity involving multiple recursive processes such as planning, translating, and reviewing (Flower & Hayes, 1981). Among these, planning is particularly critical in the early stage, as learners must generate ideas and organize content before producing written text.

From the perspective of Cognitive Load Theory (Sweller, 1988), writing tasks impose a high cognitive load because learners must simultaneously manage idea development, linguistic encoding, and task requirements. This challenge is especially pronounced among lower-proficiency learners, who may struggle to initiate writing due to limited lexical resources (Alzubi & Nazim, 2024).

In addition to cognitive constraints, affective factors such as anxiety and low confidence play a significant role. Writing anxiety has been consistently identified as a barrier to effective performance in EFL contexts (Akhtar et al., 2019; Rasool et al., 2023; Sun et al., 2024). Learners experiencing anxiety often demonstrate reduced willingness to participate and lower task engagement.

Importantly, both cognitive and affective challenges tend to emerge before writing begins, affecting learners' readiness to engage in the task. This highlights the importance of instructional support at the pre-writing stage, where learners can be prepared cognitively and emotionally for writing tasks.

2.3 Warm-up Activities and Writing Readiness

Warm-up or pre-writing activities are traditionally used as introductory stages in language lessons. However, recent research suggests that they play a more substantial role as a mechanism for enhancing writing readiness (Yuk & Yunus, 2021; Mahdi et al., 2025).

Warm-up activities typically involve low-stakes, interactive tasks such as brainstorming, vocabulary activation, or short discussions. From a cognitive perspective, these

activities facilitate idea generation and lexical retrieval, enabling learners to approach writing tasks with greater clarity (Mahdi et al., 2025). From an affective perspective, they reduce anxiety and increase confidence by providing a gradual transition into writing (Rasool et al., 2023). Behaviorally, they promote participation and establish early engagement.

These functions align with the concept of writing readiness, which includes cognitive readiness (availability of ideas), affective readiness (confidence), and behavioral readiness (willingness to engage). Unlike engagement, which occurs during task performance, readiness operates at the pre-task stage and influences how learners initiate writing.

Despite their importance, warm-up activities are often minimized in time-constrained classrooms (Nguyen-Viet & Nguyen-Viet, 2023). As a result, learners may begin writing tasks without sufficient preparation, which can negatively affect performance.

In this study, warm-up activities are positioned as the primary instructional stage where readiness can be enhanced. However, consistent with the research design, they are not assumed to directly improve writing performance but to function as an enabling condition that may indirectly support performance outcomes.

2.4 Gamification as an Indirect Support Mechanism

Gamification refers to the integration of game elements such as points, rewards, and feedback into non-game learning environments (X. Li et al., 2022). In EFL education, gamification has been widely associated with increased engagement, motivation, and participation (Zhang & Hasim, 2023; Chan & Lo, 2024).

Empirical studies indicate that gamified learning environments can enhance behavioral engagement, emotional involvement, and learning persistence (Abdulbaki et al., 2025; Boudadi et al., 2024). However, its direct impact on academic performance, particularly writing, remains less conclusive.

In writing instruction, gamification is more appropriately understood as an indirect support mechanism. Rather than directly improving writing skills, it influences mediating factors such as engagement, motivation, and anxiety reduction (Wang, 2023; Núñez-Pacheco et al., 2023). These factors may, in turn, create more favorable conditions for writing.

This distinction is essential for maintaining academic rigor and avoiding overgeneralized claims about effectiveness.

2.5 ClassDojo in Warm-up Activities

ClassDojo is a widely used digital platform that incorporates gamified features such as real-time feedback, point systems, and visual rewards. It is primarily designed for classroom management, allowing teachers to reinforce participation and monitor behavior (Corser et al., 2025; Pham, 2021).

Previous research has shown that ClassDojo and other gamified digital platforms can enhance learner engagement, participation, and classroom interaction (Sotos-Martínez et al., 2023; Phan, 2024). However, research on ClassDojo has largely focused on behavior management rather than instructional processes.

Importantly, there is limited research examining how ClassDojo can be integrated into specific instructional stages, particularly warm-up activities in writing lessons. This represents a key gap in the literature.

In the present study, ClassDojo is positioned explicitly within the warm-up stage. Its features are used to structure short, interactive activities that provide immediate feedback, encourage participation, and create a motivating environment before writing tasks. Through this integration, ClassDojo is expected to enhance learners' engagement, readiness, and motivation at the pre-writing stage.

Consistent with the study's conceptual framework, ClassDojo is not treated as a direct writing instruction tool. Instead, it functions as an indirect pedagogical support, facilitating the conditions under which writing tasks are performed.

2.6 Learner Perceptions: Technology Acceptance Model (TAM) and Self-Determination Theory (SDT) Perspectives

Learner perceptions are critical in understanding how digital tools function in educational contexts. In this study, perceptions are examined through the combined perspectives of the TAM and SDT.

TAM (Davis, 1989) explains technology acceptance through two key constructs: Perceived Usefulness (PU) and Perceived Ease of Use (PEOU). These constructs influence learners' willingness to adopt and engage with digital tools (Davis, 1989).

Complementing TAM SDT (Ryan & Deci, 2000) explains motivation in terms of psychological needs such as competence and autonomy. Gamified features such as feedback and rewards may support these needs, thereby enhancing intrinsic motivation.

Building on these frameworks, the present study examines learner perceptions across four constructs: perceived ease of use, perceived usefulness, engagement and readiness, and motivation. These constructs are operationalized through the student questionnaire and directly address the second research question.

2.7 Research Gap and Conceptual Positioning

Despite the growing body of research on gamification and digital tools in EFL education, several gaps remain.

First, existing studies have primarily focused on engagement and motivation, with limited attention to writing performance as a measurable outcome (Zhang & Hasim, 2023; Wang, 2023). Second, ClassDojo has rarely been examined within specific instructional stages, particularly the warm-up phase. Third, there is limited research integrating performance outcomes with learner perceptions within a unified framework.

These gaps are particularly evident in Vietnamese EFL contexts, where writing instruction remains challenging and the pedagogical use of gamified tools in pre-writing stages has not been systematically explored (Nguyen, 2021; Whitty et al., 2022).

To address these gaps, the present study proposes an indirect mechanism in which ClassDojo is integrated into warm-up activities to enhance learners' engagement, readiness, and motivation prior to writing tasks. These factors may, in turn, be associated with improvements in writing performance, including potential sustained effects over time. At the same time, learners' perceptions of this integration are examined through perceived usefulness, perceived ease of use, engagement and readiness, and motivation.

This conceptual positioning provides the theoretical foundation for the present study, which examines the integration of ClassDojo into warm-up activities as an indirect support mechanism for EFL learners' writing performance within a specific instructional context.

3. Methodology

The present study employed a quasi-experimental mixed-methods design to examine the integration of ClassDojo into warm-up activities and its association with EFL learners' writing performance. This design combined quantitative and qualitative approaches to capture both measurable changes in writing outcomes and learners' perceptions of the intervention.

3.1 Research Design and Participants

The quantitative component followed a non-equivalent control group design, as intact classes were used and random assignment was not feasible in the instructional context. Writing performance was measured at three points: pre-test, immediate post-test, and delayed post-test (two weeks later), allowing the study to examine both improvement and short-term retention.

The study was conducted at Nam Do Language Center (Ho Chi Minh City, Vietnam). Four KET-level classes participated. The initial sample included 86 learners; after removing incomplete cases, the final sample consisted of 73 learners (38 experimental, 35 control). Both groups followed the same curriculum, with the only difference being the integration of ClassDojo into the experimental group's warm-up activities.

3.2 Instruments

Writing performance was assessed using three tests aligned with the Cambridge A2 Key (KET) format. Each test included a communicative task and a guided writing task. Scripts were rated independently by two raters using the Cambridge analytic rubric (Content, Organisation, and Language), and the average score was used.

Inter-rater consistency was examined using Pearson's correlation coefficient. The correlations between the two raters' scores were consistently strong across the pre-test, immediate post-test, and delayed post-test, ranging from $r = .861$ to $r = .916$, all $p < .001$. Therefore, the average score of the two raters was used for further statistical analysis. The detailed inter-rater correlation coefficients are presented in Table 1.

Table 1
Inter-Rater Correlations of Writing Test Scores

Test	Group	r	p
Pre-test	Experimental	.899	< .001
Pre-test	Control	.916	< .001
Post-test	Experimental	.861	< .001
Post-test	Control	.889	< .001
Delayed post-test	Experimental	.871	< .001
Delayed post-test	Control	.908	< .001

Learners' perceptions were collected through a bilingual questionnaire administered to the experimental group. The instrument measured four constructs: perceived ease of use,

perceived usefulness, engagement and readiness, and motivation. In addition, semi-structured interviews were conducted with ten learners to gain deeper insights into their experiences.

3.3 Intervention Procedure

The intervention lasted twelve weeks, with three sessions per week. In the experimental group, ClassDojo was integrated into the warm-up stage (10–15 minutes) of each writing lesson. Activities included brainstorming, vocabulary recall, and short interactive tasks, supported by real-time feedback and participation points.

The purpose of this integration was to enhance learners' engagement and readiness prior to writing, rather than to directly teach writing. The control group followed the same instructional content without ClassDojo.

3.4 Data Collection and Analysis

Data collection followed a fixed and systematic sequence. Initially, both groups completed the pre-test to establish baseline writing performance. This was followed by the intervention period, after which the immediate post-test was administered. Subsequently, the questionnaire and semi-structured interviews were conducted with the experimental group to explore learners' perceptions. Finally, a delayed post-test was administered to both groups to examine the stability of performance over time. This structured procedure allowed the study to capture both changes in writing performance and learners' perceptions of the intervention.

Quantitative data were analyzed using descriptive statistics, paired-samples and independent-samples t-tests, and effect sizes (Cohen's d). Questionnaire data were analyzed descriptively, with internal consistency assessed using Cronbach's alpha.

Qualitative data from interviews were analyzed using thematic analysis to identify patterns related to learners' perceptions of engagement, readiness, and usefulness. Findings from both strands were integrated at the interpretation stage.

3.5 Ethical Considerations

Participants were informed about the study and participated voluntarily. All data were anonymized, and participation had no impact on academic evaluation.

4. Results

This section presents the findings in relation to the two research questions. It first reports writing performance across the experimental and control groups and then examines learners' perceptions of the ClassDojo-supported warm-up activities. These findings provide the basis for the subsequent discussion of writing performance, engagement, readiness, and motivation.

4.1. Writing Performance Outcomes

4.1.1. Baseline comparison

Before examining post-intervention outcomes, the pre-test writing scores of the experimental and control groups were compared. Table 2 presents the baseline comparison.

Table 2
Baseline Comparison of Pre-test Writing Scores

Group	N	Mean	SD	t	p

Experimental	38	15.53	5.04	0.725	.471
Control	35	14.70	4.66		

Table 2 indicates that the mean score of the experimental group was slightly higher than that of the control group. However, the difference was not statistically significant (p = .471), indicating that no statistically significant difference in pre-test writing performance was detected between the two groups. This provides a reasonable baseline for subsequent comparisons.

4.1.2. Within-group development

To investigate the developmental changes over time, writing scores of both groups were compared at pre-test, post-test, and delayed post-test phases. Table 3 provides the results.

Table 3

Within-Group Development of Writing Scores

Group	**Pre-test**	**Post-test**	**Delayed Post-test**	**Gain**
Experimental	15.53	22.36	22.58	6.83
Control	14.70	18.78	18.00	4.07

As Table 3 shows, both groups improved from pre-test to post-test, although the magnitude and maintenance of the gains differed. The experimental group showed substantial improvement from the pre-test to the post-test (gain = 6.83), and this performance was maintained at the delayed post-test. The control group also improved from pre-test to post-test (gain = 4.07), but its mean score declined slightly at the delayed stage, indicating less stable performance over time.

4.1.3. Between-group comparison

To examine between-group differences further, writing performance was compared at the post-test and delayed post-test. Table 4 presents the results.

Table 4

Between-Group Comparison of Writing Performance

Stage	**Group**	**Mean**	**SD**	**t**	**p**
Post-test	Experimental Group	22.36	4.11	3.426	.001
	Control Group	18.78	4.82		
Delayed	Experimental Group	22.58	3.44	4.469	< .001
	Control Group	18.00	5.20		

The results indicate significant differences between the two groups at both the post-test ($p = .001$) and delayed post-test ($p < .001$). The experimental group consistently outperformed the control group, demonstrating greater immediate improvement and more stable short-term retention. The wider between-group difference at the delayed stage further suggests that the observed performance advantage was maintained over the short term, whereas the control group showed a slight decline.

4.1.4. Effect size

In order to gain a better insight into the practical importance of these findings, effect sizes were computed and are shown in Table 5.

Table 5

Effect Sizes for Writing Performance

Comparison	**Cohen's d**
Experimental (Pre–Post)	1.93
Control (Pre–Post)	1.63
Between groups (Post-test)	0.80

Both groups showed substantial improvement; however, the effect was stronger in the experimental group. The between-group effect size indicates that the post-test difference was not only statistically significant but also educationally meaningful.

4.2. Learners' Perceptions

In addition to writing performance, the study also examined learners' perceptions of the ClassDojo-supported warm-up activities. The reliability of the questionnaire constructs is provided in Table 6.

Table 6

Reliability of Questionnaire Constructs

Construct	**Items**	**Cronbach's Alpha**
Ease of Use	6	.811
Usefulness	6	.852
Engagement & Readiness	6	.847
Motivation	6	.887

Internal consistency of all constructs was acceptable, indicating that the questionnaire was a reliable instrument for measuring learners' perceptions.

Learners generally reported positive perceptions of ClassDojo, particularly in terms of ease of use and usefulness. The platform was perceived as intuitive, allowing students to participate in activities with minimal difficulty. In terms of usefulness, learners indicated that the warm-up activities supported idea generation, vocabulary recall, and better understanding of writing tasks before beginning.

In addition, students reported increased engagement and readiness during the warm-up phase. The use of real-time feedback and point-based rewards encouraged active participation and helped create a more supportive learning environment. Learners also reported feeling more confident and less anxious when approaching writing tasks, and they perceived the gamified features as motivating, contributing to a more positive overall learning experience.

Translated interview data further supported the questionnaire findings. One learner stated, “When I used points, I really paid more attention.” Another student explained, “Normally I am afraid because I do not know what to write, but with the warm-up questions and points, I was more focused and felt a bit more confident.” A third participant added, “I began the writing task faster than I used to.” These responses suggest that ClassDojo-supported warm-up activities helped learners become more attentive, confident, and ready before writing.

5. Discussion

This section interprets the findings in relation to the research questions and situates them within existing theoretical and empirical literature. The discussion focuses on the role of ClassDojo-supported warm-up activities as an indirect mechanism influencing writing performance and learners’ perceptions.

5.1 ClassDojo as an Indirect Support for Writing Performance

In this study, ClassDojo did not function as a direct instructional tool for writing. It was not used to teach writing structure, provide corrective feedback, or improve linguistic accuracy directly; instead, it was integrated into the warm-up stage prior to writing tasks. Within this instructional design, the experimental group demonstrated greater improvement and more stable short-term retention than the control group.

One explanation for this finding is that ClassDojo-supported warm-up activities enhanced pre-writing conditions, particularly in terms of idea activation, readiness, and engagement. From a cognitive perspective, these activities may have reduced the processing demands during writing. According to the cognitive process model of writing (Flower & Hayes, 1981), planning is a critical stage in which learners generate and organize ideas before text production. By activating relevant vocabulary and ideas during the warm-up phase, learners were better prepared to begin writing, thereby reducing the need to manage multiple processes simultaneously.

This interpretation is further supported by Cognitive Load Theory (Sweller, 1988), which suggests that reducing cognitive load can facilitate task performance. When learners enter a writing task with pre-activated ideas and vocabulary, they may experience less cognitive overload, allowing them to allocate more resources to organizing and expressing their ideas.

In addition, the gamified features of ClassDojo may have contributed to increased engagement and attention during the pre-writing stage. Previous research has shown that gamification can enhance learner participation and emotional involvement (C. Li et al., 2024; Zhang & Hasim, 2023). In the present study, this increased engagement may have created more favorable conditions for writing, which may explain the observed differences in performance between groups.

Taken together, these findings suggest that the contribution of ClassDojo lies not in directly improving writing skills, but in enhancing the conditions under which writing occurs. This supports the view that writing performance is influenced by multiple interacting factors, including pre-task readiness and engagement.

5.2 The Role of Warm-up Activities in Writing Instruction

The findings also highlight the pedagogical importance of the warm-up stage in writing lessons. Rather than functioning as a routine or transitional activity, warm-up can be conceptualized as a structured pre-writing phase that supports learners' cognitive and emotional preparation.

In this study, warm-up activities facilitated idea generation, vocabulary recall, and increased focus, which are essential for effective writing initiation. This aligns with previous research suggesting that pre-writing support can improve learners' readiness and reduce hesitation at the early stage of writing (Yuk & Yunus, 2021; Mahdi et al., 2025).

Importantly, the results suggest that writing development begins before the act of drafting. Learners need to activate relevant knowledge, organize initial ideas, and overcome psychological barriers before they can engage effectively in writing tasks. Therefore, instructional approaches that support this preparatory phase may have a meaningful impact on overall writing performance.

This perspective extends traditional models of writing instruction by emphasizing the importance of pre-task conditions, particularly in EFL contexts where learners often struggle to initiate writing.

5.3 Contextual Suitability of ClassDojo

The observed benefits of ClassDojo in this study appear to be closely related to the characteristics of the instructional context. First, the platform provides immediate feedback and visible participation cues, which help maintain learners' attention at the beginning of the lesson. This is particularly important in warm-up activities, where initial engagement sets the tone for the rest of the lesson.

Second, the use of gamified elements such as points and visual rewards creates a more interactive and motivating classroom environment compared to traditional warm-up practices. This supports previous findings that gamification can enhance classroom interaction and learner involvement (Chan & Lo, 2024).

Furthermore, ClassDojo appeared particularly suitable for the KET-level learners in this study because of its simplicity and accessibility. The platform did not require advanced technical skills, allowing learners to participate with minimal technological demands. This alignment between tool design and learner characteristics may have contributed to the observed improvements in engagement and readiness.

These findings suggest that the success of educational technology depends not only on its features but also on its fit with the instructional context and learner needs.

5.4 Learner Perceptions: TAM and SDT Perspectives

The positive perceptions reported by learners can be interpreted through TAM (Davis, 1989). Learners perceived ClassDojo as both useful and easy to use, which likely contributed to their willingness to engage with the platform. Perceived usefulness was reflected in learners'

reports that warm-up activities supported idea generation and task understanding, while perceived ease of use was associated with the platform's intuitive design.

In addition, the findings can be explained through SDT (Ryan & Deci, 2000). The use of real-time feedback and rewards may have supported learners' sense of competence and engagement, potentially supporting learners' motivation. This is consistent with previous research showing that gamified environments can positively influence learners' motivation and emotional involvement (Abdulbaki et al., 2025).

Importantly, the study highlights engagement and readiness as potential explanatory factors rather than statistically tested mediators. Learners reported feeling more prepared, confident, and less anxious before writing, suggesting that the intervention was associated with changes in their pre-task state. This supports the view that learner perceptions, engagement, and performance outcomes may be closely related.

5.5 Pedagogical and Theoretical Implications

Pedagogically, the findings suggest that teachers should treat warm-up activities as structured pre-writing support rather than routine introductory tasks. In EFL writing lessons, warm-up activities can be designed to activate learners' ideas, support vocabulary recall, and increase readiness before the main writing task. Simple gamified tools such as ClassDojo may help teachers create a more interactive and motivating pre-writing environment without requiring complex technological integration. By using features such as immediate feedback and participation rewards, teachers can encourage learners to become more focused, confident, and prepared before writing.

Theoretically, this study contributes to the understanding of writing instruction by emphasizing the role of pre-task conditions in shaping writing performance. The findings support the view that engagement and readiness are important factors in the writing process, particularly for lower-proficiency EFL learners. In addition, the study contributes to the literature on gamification by showing that gamified tools may operate as indirect support mechanisms. Rather than directly improving writing skills, ClassDojo may support learners' motivation, emotional readiness, and participation, thereby creating more favorable conditions for writing performance.

6. Conclusion

This study examined the integration of ClassDojo into warm-up activities as a form of pedagogical support for EFL writing instruction in a Vietnamese language center. Rather than functioning as a direct instructional tool, ClassDojo was embedded in the pre-writing phase to enhance learners' engagement, readiness, and motivation prior to writing tasks.

The findings indicated that the experimental group demonstrated greater improvement in writing performance than the control group. This improvement was observed at the immediate post-test and was maintained at the delayed post-test, suggesting more stable short-term retention. In addition, learners reported generally positive perceptions of the ClassDojo-supported warm-up activities, particularly in terms of perceived ease of use, perceived usefulness, engagement and readiness, and motivation.

Taken together, these results suggest that ClassDojo can support writing development indirectly by enhancing the conditions under which writing occurs. The platform may contribute to a more supportive pre-writing environment by facilitating idea generation, increasing learner engagement, and improving readiness to write.

From a pedagogical perspective, the findings highlight the importance of the warm-up phase in writing instruction. Teachers may benefit from designing structured pre-writing activities that support both cognitive and affective preparation. In this context, simple gamified tools such as ClassDojo offer a practical and accessible way to enhance learner participation without introducing unnecessary complexity.

Several limitations should be acknowledged. The study employed a quasi-experimental design using intact classes, which limits the strength of causal inferences. In addition, the research was conducted within a single language center with KET-level learners, which may affect the generalizability of the findings. The relatively short duration of the intervention should also be considered when interpreting the results.

Future research may explore the effectiveness of similar interventions across different proficiency levels and over longer periods of time. Further studies could also investigate other forms of technology-supported warm-up activities and their potential impact on writing performance in EFL contexts.

Overall, the study suggests that even modest adjustments in instructional design, particularly at the pre-writing stage, can contribute to meaningful differences in learner outcomes. Practical and user-friendly tools such as ClassDojo may offer valuable support for enhancing engagement and writing development in EFL classrooms.

Acknowledgments

The authors would like to express sincere gratitude to the management and teaching staff at Nam Do Language Center for their support in facilitating this study. Special thanks are extended to the students who participated in the research for their time and cooperation. The authors also appreciate the valuable guidance and feedback from academic supervisors and colleagues throughout the research and writing process.

#79 EXPLORING THE EFFECTS OF AI-MEDIATED LOW-STAKES PRACTICE ON SPEAKING ANXIETY IN VIETNAMESE EFL CLASSROOMS: A QUASI-EXPERIMENTAL STUDY

Minh Hang Le[1]

Abstract

Speaking anxiety continues to constrain learners' participation and oral performance in English-as-a-Foreign-Language (EFL) classrooms. Although recent work has examined the use of artificial intelligence (AI) in language learning, its role in addressing affective factors remains insufficiently investigated. This study examines the effects of AI-mediated low-stakes practice on speaking anxiety among Vietnamese university students. A quasi-experimental design was implemented with two intact classes of 64 second-year English-major students at a Vietnamese university. The experimental group engaged in AI-supported speaking activities, including guided role-plays and repeated practice using conversational AI tools over a six-week period, while the control group followed conventional speaking instruction. Data were collected through pre- and post-tests using a speaking anxiety questionnaire adapted from the Foreign Language Classroom Anxiety Scale (FLCAS) and an analytic speaking rubric. The results indicate that students in the experimental group reported significantly lower levels of speaking anxiety and higher levels of confidence compared to those in the control group. Student feedback further suggests that AI-mediated practice enabled repeated, low-pressure exposure and reduced concerns about negative evaluation. The findings provide empirical support for the integration of AI-mediated low-stakes activities in speaking instruction as a means of addressing affective constraints and supporting learner participation in EFL contexts.

Keywords: AI-mediated learning, speaking anxiety, low-stakes practice, EFL classrooms, quasi-experimental design

1. Introduction

Speaking is widely regarded as the most anxiety-provoking skill in foreign language learning (Horwitz et al., 1986; Young, 1991). Horwitz et al. (1986) identified three interrelated components of foreign language anxiety (FLA): communication apprehension, fear of negative evaluation, and test anxiety. Subsequent factor-analytic work confirmed the distinctiveness of speaking anxiety within the broader FLA construct (Aida, 1994). Of these three components, fear of negative evaluation has been most consistently associated with speaking reticence in EFL contexts (MacIntyre & Gardner, 1994; Teimouri et al., 2019; Young, 1991). In English-as-a-Foreign-Language (EFL) settings, speaking anxiety frequently undermines participation and overall oral performance (Liu & Jackson, 2008; Woodrow, 2006). Meta-analytic evidence confirms that the negative relationship between anxiety and L2 achievement is robust, with speaking consistently the most susceptible domain (Teimouri et al., 2019).

[1] *Lecturer, Faculty of Foreign Languages, Ton Duc Thang University, Ho Chi Minh City, Vietnam*

Vietnamese EFL classrooms present a particularly acute instance. Large class sizes, examination-oriented curricula, and Confucian-heritage norms that privilege face preservation interact synergistically to compound speaking anxiety (Bao, 2013). Truong and Ho (2022), in a study of 297 Vietnamese freshmen, confirmed that speaking anxiety remains pervasive, with communication apprehension, fear of negative evaluation, and test anxiety all contributing to students' reluctance to speak. Tran and Moni (2015) further showed that Vietnamese learners' reticence was mediated by collectivist norms of passive reception. Despite the well-documented severity of this problem, no systematic attempt has been made to investigate whether emerging AI technologies can alleviate speaking anxiety in Vietnamese higher education. This absence is particularly problematic given that Vietnam's Ministry of Education and Training has actively promoted technology integration in foreign language teaching, yet empirical evidence to guide AI-mediated pedagogical practices in this context remains unavailable.

The motivation for this study arose from a recurring observation in Vietnamese university speaking classrooms: students who demonstrate strong grammatical knowledge and reading comprehension in written assessments become visibly anxious and largely silent when asked to speak. In typical large speaking classes, it is not uncommon for only a handful of students to voluntarily contribute to oral activities, while the majority resort to rehearsed scripts or avoid eye contact to escape being called upon. This persistent gap between what students know and what they are willing to say motivated the present investigation into whether AI-mediated practice could offer a way to break the cycle of silence.

Against this backdrop, voice-enabled AI platforms now allow learners to practice speaking without the social pressure of face-to-face interaction (Fathi et al., 2024; Huang et al., 2022). For the purposes of this study, low-stakes practice is operationally defined as speaking activities that: (a) are not formally graded, (b) do not involve real-time performance before a peer or instructor audience, and (c) permit self-paced repetition without social consequence. This definition draws on the desirable difficulties framework (Bjork & Bjork, 2011) and recent AI-mediated speaking research (Fryer et al., 2019; Fathi et al., 2024).

The theoretical rationale draws on Krashen's (1982) affective filter hypothesis and Horwitz et al.'s (1986) tripartite model. Despite acknowledged limitations regarding empirical testability (McLaughlin, 1987), the affective filter remains a productive heuristic, and its core prediction—that reducing anxiety facilitates acquisition—continues to receive empirical support (Teimouri et al., 2019). AI-mediated practice may lower this filter by targeting two of the three FLA components. Fear of negative evaluation is reduced because the AI interlocutor is non-judgmental and does not relay performance information to peers. Communication apprehension is attenuated because private, repeatable practice removes real-time audience pressure. Empirical support for these mechanisms comes from Zhang et al. (2024), who found reduced anxiety and increased enjoyment among Chinese EFL learners using AI chatbots, and Fathi et al. (2024), who reported improved speaking skills in an AI-mediated experimental condition. Test anxiety, tied to formal assessment contexts, is less directly addressed.

A necessary caveat, however, is that AI-mediated interaction is not anxiety-neutral. Speech recognition failures, unnatural turn-taking, and the sheer unfamiliarity of talking to a machine could partially offset the benefits of a non-evaluative practice space (El Shazly, 2021). Recent findings suggest such frustrations diminish as familiarity develops (Chen et al., 2025; Fathi et al., 2024).

The empirical base, though growing rapidly, remains thin and geographically uneven. Fathi et al. (2024), in a true experimental study with 40 Iranian EFL learners, found significant

improvements in speaking skills, though the small sample limits statistical power. Zhang et al. (2024) reported reduced anxiety among 99 Chinese students with moderate effect sizes. Chen et al. (2025) found significant anxiety reductions with 71 Chinese learners over eight weeks. Wu et al. (2026) demonstrated reduced anxiety among 75 Indonesian students. These studies span East Asian, Middle Eastern, and Southeast Asian contexts, but none has examined Vietnamese higher education. A systematic search of Scopus, Web of Science, and ERIC in January 2025 using ("artificial intelligence" OR "chatbot" OR "AI") AND ("speaking anxiety" OR "oral anxiety" OR "FLSA") AND ("Vietnam*") in titles, abstracts, and keywords yielded zero results.

The present study was designed to fill this void. The inclusion of oral performance as a dependent variable is theoretically motivated: if AI-mediated practice lowers the affective filter, learners should show greater willingness to attempt output and increased engagement with input, facilitating gains in fluency and interactional competence (Krashen, 1982). Furthermore, repeated practice may develop procedural knowledge through automatization (DeKeyser, 2007). By examining anxiety sub-components alongside oral performance and learner perceptions, this study contributes not only contextual evidence from Vietnam but also a more fine-grained understanding of how AI-mediated low-stakes practice may influence affective and communicative dimensions of EFL speaking development. Accordingly, this study pursues three specific objectives: (1) to measure the effect of AI-mediated low-stakes practice on total and sub-component speaking anxiety; (2) to assess whether anxiety reduction translates into measurable improvements in oral performance; and (3) to explore students' lived experiences with AI-mediated practice through qualitative inquiry. The study is guided by the following research questions:

RQ1: To what extent does AI-mediated low-stakes speaking practice reduce foreign language speaking anxiety among Vietnamese EFL university students?

RQ2: What are the effects of AI-mediated low-stakes speaking practice on students' oral performance as measured by an analytic speaking rubric?

RQ3: How do students in the experimental group perceive the role of AI-mediated practice in their speaking anxiety reduction and confidence development?

2. Literature Review

2.1. Methodological Evolution in AI-Mediated Speaking Research

The rapid proliferation of generative AI tools has prompted a wave of review studies mapping the evolving landscape. Crompton et al. (2024), in a systematic review of 42 studies on AI in English language teaching, found that speaking was among the skills most frequently supported by AI, yet affective outcomes remained underexamined. Koç and Savaş (2025), in a meta-synthesis of 57 studies on voice-based AI chatbots, noted a conspicuous absence of research applying the FLA framework to AI-mediated speaking practice. Earlier work focused primarily on cognitive and linguistic outcomes. Bibauw et al. (2019) synthesized dialogue-based CALL findings and reported moderate effects on vocabulary and grammar, noting that affective outcomes were rarely primary variables. Huang et al. (2022) concluded that most chatbot studies emphasized linguistic accuracy over anxiety. Kim et al. (2019) and Jeon (2024) provided early qualitative evidence that learners valued non-judgmental AI interaction, but both lacked control groups. The landscape has since improved: Fathi et al. (2024) employed a true experimental design, Zhang et al. (2024) included validated anxiety instruments, and Chen et al. (2025) demonstrated that longer interventions (eight weeks) may yield more robust affective outcomes. Wu and Li (2026), in a recent meta-analysis, reported a substantial overall

effect of AI-enhanced instruction on speaking proficiency, though affective outcomes were not separately meta-analyzed. However, no study has examined sub-component effects across the FLA construct (CA, FNE, TA separately). In summary, existing studies demonstrate promising effects of AI-mediated speaking practice, but three limitations persist: limited attention to affective mechanisms beyond total anxiety scores, underrepresentation of Vietnamese and other ASEAN learners, and insufficient analysis of how AI practice differentially affects FLA sub-components. The present study addresses all three gaps.

2.2. The Vietnamese EFL Context: Sociocultural Amplifiers

Bao (2013) argued that Confucian-heritage values create a deference-to-authority dynamic rendering student-initiated speech an implicit norm violation. Truong and Ho (2022), surveying 297 Vietnamese freshmen, found that all three FLA components contributed to speaking anxiety, with assessment-related concerns particularly salient, suggesting that Vietnamese examination-oriented culture may intensify FLA beyond what is observed in contexts with more formative evaluation traditions. This profile suggests that an AI-mediated intervention could be particularly effective in Vietnam, but also raises the question of whether technology anxiety may be more pronounced in developing infrastructure contexts. Ngo (2023) found generally positive perceptions of ChatGPT among Vietnamese university students, but did not address speaking skills or anxiety.

2.3. Desirable Difficulties and the Affective Filter: Convergent Frameworks

This study draws on two convergent frameworks. Krashen's (1982) affective filter operates at the input-processing level: anxiety blocks comprehensible input. The desirable difficulties framework (Bjork & Bjork, 2011) operates at the practice-design level: optimal learning requires challenge without threat. They converge in predicting that low-stakes AI practice should benefit learners but differ in mechanism—reduced input blockage (Krashen) versus optimized practice conditions (Bjork & Bjork). The mixed-methods design allows exploration of both: quantitative anxiety reduction maps onto the affective filter, while qualitative reports of automatization map onto desirable difficulties. Additionally, DeKeyser's (2007) skill acquisition framework predicts that repeated practice develops procedural knowledge, enabling more fluent production—directly testable through dimension-level speaking performance analysis.

3. Methodology

3.1. Research Design

This study employed a quasi-experimental pretest–posttest non-equivalent control group design (Creswell & Creswell, 2018). Two intact classes of second-year English-major students at a Vietnamese university were assigned as experimental (n = 32) and control (n = 32) groups. The two classes were purposively selected based on comparable prior-semester GPA in English skills courses, equivalent CEFR placement results (B1 or above, as determined by the university's standardized placement test), and similar instructor-reported participation patterns from the preceding semester.

3.2. Participants

A total of 64 second-year English-major students participated. All were Vietnamese nationals aged 19–21 at a public university in Ho Chi Minh City. The two intact classes each enrolled 43 students; however, participation was voluntary, and only students who provided informed consent were included. In each class, 32 students consented, while the remaining students—most of whom were retaking the course and declined the additional practice

commitment—were not enrolled in data collection, yielding a final sample of 64. The experimental group consisted of 32 students (24 female, 8 male) and the control group of 32 students (22 female, 10 male). All had achieved at least B1 on the CEFR as determined by the university's standardized placement test. Prior AI experience was assessed via a screening questionnaire administered during recruitment; no participant reported prior sustained use of conversational AI tools for English speaking practice. Ethical approval was obtained from the university's Institutional Review Board (IRB), and all participants provided written informed consent. No participants withdrew during the study period; all 64 completed both pretest and posttest assessments.

3.3. Instruments

3.3.1. Speaking anxiety questionnaire

Speaking anxiety was measured using a 20-item questionnaire adapted from the 33-item FLCAS (Horwitz et al., 1986). Items were selected through a two-stage process: first, two applied linguistics experts independently identified items specifically relevant to speaking anxiety (excluding items pertaining solely to reading, writing, or general classroom behavior); second, items with factor loadings below .40 in prior validation studies were excluded. The resulting 20-item instrument comprised communication apprehension (8 items), fear of negative evaluation (7 items), and test anxiety (5 items) subscales. Items used a five-point Likert scale (1 = strongly disagree to 5 = strongly agree; total range: 20–100). The instrument was piloted with 30 students from a non-participating class. Cronbach's alpha for the total scale was .89; subscale alphas were .84 (CA), .86 (FNE), and .78 (TA), all exceeding the .70 threshold recommended for research instruments. A Vietnamese translation was provided following back-translation procedures (Brislin, 1970).

3.3.2. Analytic speaking rubric

Oral performance was assessed using an analytic rubric adapted from Luoma (2004), evaluating fluency, pronunciation, grammatical accuracy, vocabulary range, and interactional competence on a 1–5 scale (maximum 25). Two trained raters—both experienced EFL lecturers—underwent a three-hour calibration session in which they independently scored 10 practice samples, discussed discrepancies, and reached consensus on scoring criteria. During data collection, both raters independently scored all 128 speaking samples (64 participants × 2 time points) while blind to group membership and time point. Scoring disagreements exceeding one point on any dimension were resolved through discussion to consensus. A two-way mixed-effects ICC computed on all 128 samples yielded .91, indicating excellent agreement (Koo & Li, 2016).

3.3.3. Semi-structured interview guide

A semi-structured interview guide consisting of eight open-ended questions addressed students' experiences with the AI tool, perceived changes in anxiety and confidence, and suggestions for improvement. Twelve experimental-group participants were selected based on pretest FLCAS scores: four from the top quartile (high anxiety), four from the middle quartiles (moderate), and four from the bottom quartile (low anxiety). Interviews were conducted individually in Vietnamese by a research assistant not involved in teaching the course, to minimize social desirability effects. Each interview lasted approximately 20–30 minutes, was audio-recorded with participant consent, and was transcribed verbatim. Transcripts were member-checked by sending summaries to participants for verification.

3.4. Intervention Design

The six-week intervention was embedded within the regular Speaking Skills II course. Both groups received the same weekly two-hour face-to-face class, taught by the same instructor using identical lesson plans and materials, to control for instructor effects. The experimental group additionally completed three 30-minute AI-mediated speaking sessions per week using ChatGPT (GPT-4o voice mode), which supports real-time voice-based conversation and automatic speech recognition. The platform provides implicit corrective feedback through conversational recasts, pronunciation modeling via text-to-speech output, and vocabulary suggestions within conversational context, though it does not offer systematic grammar correction or scored pronunciation assessment. Compliance was monitored through weekly self-report logs verified against conversation screenshots (mean compliance: 87%; range: 72–97%). Activities were scaffolded:

Weeks 1–2: Guided role-plays. Structured scenarios with scripted prompts and vocabulary support.

Weeks 3–4: Semi-guided conversations. Topic-based conversations with minimal structural support.

Weeks 5–6: Open-ended discussions. Self-selected topics simulating naturalistic spoken interaction.

The control group completed equivalent speaking preparation tasks, including recorded self-practice monologues, textbook-based speaking prompts, and vocabulary rehearsal logs (approximately 90 minutes/week), but without interactive AI-mediated oral practice. Thus, the comparison is between AI-mediated interactive speaking practice and non-interactive conventional preparation tasks.

3.5. Data Collection

At both pretest (Week 1) and posttest (Week 6), data collection followed a fixed sequence: participants first completed the speaking anxiety questionnaire in a private setting, then proceeded to the individual speaking assessment. This order was chosen to capture anxiety levels prior to the potential stress of the speaking task. Speaking assessments involved a three-minute conversation with a trained interlocutor (the same interlocutor at both time points) on a topic drawn randomly from a pool of 10 pre-validated topics. Different topics were assigned at pretest and posttest to minimize practice effects. Conversations were audio-recorded and rated by two raters blind to group membership and time point.

3.6. Data Analysis

Quantitative data were analyzed using SPSS (Version 28). Mixed-design ANOVAs examined changes in anxiety and performance. Effect sizes were reported using η^2p and Cohen's d (calculated as the within-group mean difference divided by the pooled standard deviation of pretest and posttest scores) with 95% confidence intervals. An ANCOVA was performed with pretest scores as covariate. Normality (Shapiro-Wilk) and homogeneity of variance (Levene's) were verified. Given the multiple sub-component (3) and dimension-level (5) analyses, a Bonferroni-adjusted alpha of .006 was applied for the sub-component tests and .01 for the dimension-level tests; however, results are also reported at the conventional .05 level for transparency. Qualitative data were analyzed inductively using thematic analysis (Braun & Clarke, 2006): transcripts were open-coded without a priori categories, and codes were iteratively grouped into themes. A second researcher independently coded 25% of transcripts ($\kappa = .81$).

3.7. Delimitations

This study is delimited in several respects. First, it is confined to second-year English-major students at a single public university in Ho Chi Minh City; findings may not generalize to non-English majors, private universities, or other regions. Second, the AI tool is limited to ChatGPT (GPT-4o voice mode); other platforms may yield different results. Third, the study examines short-term effects over six weeks; long-term retention falls outside its scope. Fourth, speaking performance is assessed via a researcher-designed analytic rubric rather than a standardized proficiency test. Fifth, the study does not measure technology proficiency or digital literacy as moderating variables.

4. Results

4.1. Baseline Comparability

Independent samples t-tests confirmed no significant pretest differences for total speaking anxiety, $t(62) = 0.21$, $p = .834$, $d = 0.05$, or speaking performance, $t(62) = 0.23$, $p = .820$, $d = 0.06$, nor across any anxiety sub-component (all $p > .70$).

4.2. Effects on Speaking Anxiety (RQ1)

Normality was confirmed (Shapiro-Wilk, all $p > .05$) and homogeneity of variance satisfied (Levene's, all $p > .70$). Descriptive statistics are presented in Table 1.

Table 1

Descriptive Statistics for Total Speaking Anxiety Scores by Group and Time

Group	Pre M	Pre SD	Post M	Post SD	Diff.	d [95% CI]
Exp. (n=32)	72.41	9.83	58.63	10.14	−13.78	1.38 [0.98, 1.78]
Ctrl. (n=32)	71.88	10.27	69.22	9.91	−2.66	0.26 [−0.13, 0.65]

The mixed-design ANOVA revealed a significant main effect of time, $F(1, 62) = 48.73$, $p < .001$, $\eta^2p = .44$; a significant Group × Time interaction, $F(1, 62) = 31.56$, $p < .001$, $\eta^2p = .34$; and a significant main effect of group, $F(1, 62) = 7.41$, $p = .008$, $\eta^2p = .11$. Post hoc pairwise comparisons indicated that the experimental group's anxiety scores decreased significantly from pretest to posttest ($M = 72.41$ to $M = 58.63$; mean difference = 13.78, $p < .001$, $d = 1.38$, 95% CI [0.98, 1.78]), while the control group showed a small, non-significant decrease ($M = 71.88$ to $M = 69.22$; mean difference = 2.66, $p = .187$, $d = 0.26$, 95% CI [−0.13, 0.65]). The ANCOVA with pretest scores as covariate confirmed these findings, $F(1, 61) = 29.84$, $p < .001$, $\eta^2p = .33$, indicating that the between-group difference was not attributable to pretest variation.

Sub-component analysis (Table 2) revealed differential effects. The experimental group showed reductions across all three sub-components: communication apprehension decreased by 6.22 points ($d = 1.29$), fear of negative evaluation by 5.94 points ($d = 1.47$), and test anxiety by 1.62 points ($d = 0.44$). In standardized terms, the effect was largest for FNE, followed by CA, with TA showing only a small effect. Significant Group × Time interactions were found for FNE, $F(1, 62) = 24.81$, $p < .001$, $\eta^2p = .29$, and CA, $F(1, 62) = 18.63$, $p < .001$, $\eta^2p = .23$, but not for TA, $F(1, 62) = 1.94$, $p = .169$, $\eta^2p = .03$. This pattern confirms the theoretical

prediction that AI-mediated low-stakes practice primarily targets evaluative and communicative anxiety while leaving assessment-related anxiety relatively unchanged.

Table 2

Anxiety Sub-Component Scores by Group and Time

Component	*Group*	*M*	*SD*	*M*	*SD*	*Diff.*	*d*
CA (8 items)	Exp.	29.38	4.71	23.16	4.93	−6.22	1.29
	Ctrl.	28.94	5.02	27.88	4.86	−1.06	0.21
FNE (7 items)	Exp.	25.47	3.88	19.53	4.22	−5.94	1.47
	Ctrl.	25.19	4.13	24.13	3.97	−1.06	0.26
TA (5 items)	Exp.	17.56	3.41	15.94	3.87	−1.62	0.44
	Ctrl.	17.75	3.53	17.21	3.44	−0.54	0.15

*CA = Communication Apprehension; FNE = Fear of Negative Evaluation; TA = Test Anxiety.

4.3. Effects on Speaking Performance (RQ2)

The mixed-design ANOVA revealed a significant Group × Time interaction, $F(1, 62) = 12.37$, $p < .001$, $\eta^2p = .17$ (Table 3). The experimental group's mean performance score increased from 14.72 (SD = 3.18) to 18.41 (SD = 2.96), a gain of 3.69 points (d = 1.20, 95% CI [0.82, 1.58]). The control group also improved, from 14.53 (SD = 3.41) to 15.88 (SD = 3.27), a gain of 1.35 points (d = 0.40, 95% CI [0.02, 0.78]). Dimension-level analysis (Table 4) indicated significant Group × Time interactions for fluency ($p < .01$), vocabulary ($p < .05$), and interactional competence ($p < .01$), but non-significant interactions for pronunciation ($p = .083$) and grammatical accuracy ($p = .114$).

Table 3

Total Speaking Performance Scores by Group and Time

	Pretest		*Posttest*			
Group	*M*	*SD*	*M*	*SD*	*Diff.*	*d [95% CI]*

4.4. Student Perceptions (RQ3)

Thematic analysis of the 12 interviews yielded four themes addressing the two dimensions of RQ3: Themes 1 and 2 illuminate the anxiety-reduction dimension, Theme 3 addresses the confidence-development dimension, and Theme 4 captures perceived limitations that contextualize the overall experience.

4.4.1. Reduced fear of judgment (10/12)

Ten participants identified the absence of social evaluation as the primary benefit. Hoa (high-anxiety) explained that with the AI, she could focus entirely on expressing ideas. Minh (moderate-anxiety) noted he could attempt longer sentences without fear of losing face. Two participants (Linh and Quang) did not identify this as primary, noting they had not experienced high evaluative anxiety prior to the intervention.

4.4.2. Benefits of repetition and self-pacing (9/12)

Nine participants valued repeating scenarios. Trang practiced a restaurant role-play seven times; by the fourth attempt, she no longer paused for vocabulary. Duc appreciated the AI's patience. Three participants found repetition less valuable, with An noting it became monotonous after the third week.

4.4.3. Gradual confidence building (8/12)

Eight participants described increasing confidence that transferred to classroom settings. Lan, who had never voluntarily spoken in class during three semesters, raised her hand after four weeks of AI practice. Four participants did not report classroom transfer, though they acknowledged greater comfort with the AI itself.

4.4.4. Perceived limitations (12/12)

All 12 identified limitations. Nine mentioned speech recognition errors with Vietnamese-accented English. Seven noted limited conversational depth. Five expressed that the AI could not replace human interaction's spontaneity. Duc captured the prevailing sentiment: the AI was like a gym—useful for building strength but not the same as playing a real sport.

5. Discussion

The central finding is straightforward: six weeks of AI-mediated practice produced a large reduction in overall speaking anxiety. The experimental group demonstrated a large anxiety reduction ($d = 1.38$, 95% CI [0.98, 1.78]), consistent with findings from Iranian (Fathi et al., 2024), Chinese (Chen et al., 2025; Zhang et al., 2024), and Indonesian (Wu et al., 2026) contexts. This study extends the evidence to Vietnamese higher education.

What sets this study apart, however, is the sub-component analysis. FNE showed the largest reduction ($d = 1.47$), CA the second ($d = 1.29$), while the TA interaction was non-significant ($p = .169$). This differential pattern—unprecedented in the AI-mediated speaking literature, where previous studies report only total scores—aligns with the theoretical rationale: AI removes the evaluative audience (reducing FNE) and provides private interaction (reducing CA) but does not simulate formal assessment (leaving TA unchanged). The qualitative findings directly support this quantitative pattern. Theme 1 (reduced fear of judgment), reported by 10 of 12 participants, corresponds to the FNE reduction; Theme 2 (benefits of repetition and self-pacing) corresponds to the CA reduction, as private practice removes the real-time audience

pressure that triggers communication apprehension. That TA was minimally affected is consistent with Theme 4, in which no participant reported reduced test-related concerns.

The performance data tell a complementary story. Fluency and interactional competence showed the largest gains, consistent with Wu et al. (2026). Pronunciation ($p = .083$) and grammatical accuracy ($p = .114$) did not show significant differential improvement, indicating that conversational AI practice alone is insufficient for accuracy-related skills requiring explicit metalinguistic instruction. These limitations mirror the system constraints noted by Hsu et al. (2023) and El Shazly (2021). The practical takeaway is clear: AI practice should be supplemented with targeted pronunciation and grammar instruction. The control group also improved modestly ($d = 0.40$, 95% CI [0.02, 0.78]), likely attributable to the regular classroom instruction both groups received. The differential gain, however, demonstrates that AI-mediated practice conferred benefits substantially beyond what conventional instruction alone provided.

The qualitative finding that participants developed automatic responses through repetition is consistent with DeKeyser's (2007) skill acquisition framework: procedural knowledge develops through practice, enabling production with reduced cognitive effort. The transfer of confidence to classroom settings, reported most vividly by Lan, suggests that automaticity gained through AI practice frees cognitive resources during face-to-face interaction. Duc's gym metaphor captures the complementary role participants attributed to AI practice, a view consistent with sociocultural theory's insistence that authentic human interaction remains essential for full communicative development (Lantolf & Thorne, 2006).

Lan's trajectory is not an isolated case but rather representative of a broader pattern observable in Vietnamese EFL classrooms: once a learner breaks the initial barrier of voluntary speaking — even once — subsequent participation becomes progressively easier. What the AI practice appears to have provided is a safe rehearsal space where that first breakthrough could occur without the social risk that the classroom entails. Various strategies have been attempted to reduce speaking anxiety in this context — pair work, anonymous response systems, small-group rotations — but none addresses the root problem as directly as removing the human audience altogether. The AI tool does precisely this, and the fact that the confidence built in private practice transferred to public classroom participation suggests that the underlying mechanism is not avoidance of speaking but rather graduated exposure. This raises the practical question of how to systematically scaffold learners from low-stakes AI practice toward high-stakes human interaction. The present findings suggest a graduated transfer pathway: after the initial weeks of private AI practice, instructors can introduce progressively more exposed speaking contexts—first paired peer conversations, then small-group discussions, and finally whole-class presentations—so that the confidence built in the non-evaluative AI environment is incrementally tested against increasingly authentic social conditions. In this model, AI practice is not an endpoint but the first rung of an anxiety-graded ladder, with each subsequent step reintroducing a controlled degree of the evaluative pressure that AI practice initially removes.

5.1. Limitations and Directions for Future Research

Several limitations should be acknowledged. First, the quasi-experimental design does not permit full causal inference. Second, the novelty of AI interaction may have generated a Hawthorne effect: engagement with novel technology, rather than the specific anxiety-reducing affordances, may partially explain results. Future research should include a technology-active control group (e.g., using AI for non-speaking tasks) to isolate oral AI practice effects from technology novelty. Third, despite compliance monitoring (87%), self-reported logs may

overestimate engagement. Fourth, the sample was limited to English-major students at a single university, and the gender distribution (predominantly female in both groups) may limit generalizability given documented gender differences in FLA (Teimouri et al., 2019). Fifth, the six-week period may not capture long-term trajectories or regression effects. A further consideration concerns technological equity: although all participants in this study had reliable access to a smartphone and internet connection, this cannot be assumed universally across Vietnamese higher education, where disparities in device ownership and network quality persist between urban and rural student populations. Instructors adopting AI-mediated practice should audit student access in advance and provide institutional alternatives—such as computer-lab sessions or shared devices—to ensure the intervention does not inadvertently disadvantage learners with limited technological resources. Future studies should employ physiological anxiety measures, delayed posttests, multi-site designs, and comparisons of AI platform types (cf. Wang et al., 2024).

6. Conclusion

This study makes two primary contributions. First, it is the first empirical study to examine AI-mediated speaking practice and language anxiety in Vietnamese higher education, extending the evidence base beyond the East Asian, Middle Eastern, and Southeast Asian contexts investigated to date. Second, it is the first AI intervention study to demonstrate differential effects across FLA sub-components, providing granular support for the theoretical claim that AI practice targets evaluative and communicative anxiety rather than producing undifferentiated reduction. Practically, the findings offer a concrete strategy for integrating AI tools as a structured supplement—not a replacement—for conventional speaking instruction. In the context of Vietnamese higher education, where speaking anxiety remains persistent and culturally reinforced, AI-mediated low-stakes practice may serve as a promising supplementary strategy, particularly when integrated with teacher-guided speaking instruction and targeted pronunciation and grammar practice. It should be emphasized that these findings do not suggest replacing teacher-led speaking instruction with AI tools. Rather, they point to a specific and limited role for AI: as a confidence-building bridge between the safety of silent knowledge and the risk of public speech. In the Vietnamese university context, where class sizes make individualized speaking practice virtually impossible and where cultural norms discourage the trial-and-error that fluency development requires, this bridge is not a luxury but a pedagogical necessity. These findings translate into several actionable recommendations for EFL instructors. First, conversational AI should be introduced as a structured homework component—three 30-minute sessions per week with scaffolded tasks progressing from guided role-plays to open-ended discussions over a six-week cycle. Second, AI practice should be explicitly positioned as a fluency and interaction builder; instructors should continue providing direct pronunciation instruction and explicit grammar teaching in class. Third, a one-week familiarization phase should precede formal practice, as qualitative data indicate technology-related frustrations diminish rapidly after initial sessions. Fourth, compliance should be monitored through weekly logs with screenshot verification. Fifth, periodic debriefing sessions should be conducted in which students discuss their AI practice experiences, facilitating metacognitive awareness of anxiety reduction. These guidelines are implementable within existing Vietnamese university curricula without requiring additional institutional resources beyond student access to a smartphone or computer with internet connectivity. Crucially, this design integrates into existing curricula without encroaching on regular class hours: the AI sessions function as structured, self-paced homework completed outside class, while in-class time is reserved for teacher-led feedback, error correction, and the graduated peer-interaction activities described above. This arrangement follows a flipped-classroom logic, in which low-

stakes rehearsal occurs privately at home and valuable face-to-face class time is devoted to the higher-order communicative work that AI cannot replicate. For a typical three-credit speaking course, the three weekly AI sessions add roughly ninety minutes of out-of-class practice—comparable to conventional homework loads—and therefore impose no additional burden on scheduled instruction.

#80 INSTRUCTORS' DIGITAL COMPETENCE AFFECTING STUDENT FEEDBACK AND PERSONALIZED LEARNING IN UNIVERSITY EDUCATION

Nguyen Thanh Tuan[1], Nguyen Phuong Bao Tran[2]

Abstract

In the context of digital transformation, instructors' digital competence has become a crucial factor affecting teaching quality and students' learning experience. Digital competence is not simply a capability of using technology, but it also includes integrating digital tools to design lessons, evaluate, provide feedback, and support learning effectively. However, feedback practice and personalized learning are still a research gap, especially in university education; both lecturers and students need to adapt to digital technology. The study aims to discover the effect of digital competence on students' feedback and personalized learning. The quantitative approach with a cross-sectional survey design is mainly applied to this study, including observation, document analysis, and a questionnaire. Data collection is done through the questionnaire, measuring three main variables: instructors' digital competence, feedback quality, and personalized learning level. Especially, the data analysis is based on the SEM model (SmartPLS4) to test research hypotheses and evaluate the relationship among variables. The expected results show the positive effect of digital competence on feedback effectiveness and personalized learning. Instructors with good capabilities of using technology can integrate digital tools to provide in-time feedback, transparency, and flexibility to meet learning needs. Effective feedback, which can strongly promote autonomous learning by supporting students with self-regulated strategies, is the intermediary element between digital competence and personalized learning. The study significantly contributes to developing professional training programs for instructors, establishing a theoretical foundation of digital competence, creating a flexible learning environment with a student-centered approach, and providing positive feedback to meet students' learning needs effectively.

Keywords: digital competence, student feedback, personalized learning, self-regulated learning, autonomous learning, digital technology, online teaching…

1. Introduction

The rapid change of digital competence has influenced teaching and learning approaches in university education in Viet Nam, Particularly Hong Bang International University. In this context, instructors' digital competence is not only about the use of technology but also about the ability to integrate it effectively into teaching activities. One of the factors directly affected by instructors is feedback, considered the most powerful tool for improving students' learning outcomes. However, the effectiveness of feedback depends on how it is designed, personalized, and how HIU instructors and students interact. Alongside that, personalized learning is increasingly receiving attention as a modern educational trend, in which content and learning approach need to be adjusted to fit each student. Digital technology plays an important role in personalized support, but this belongs to instructors' digital

[1] *Can Tho University; Hong Bang International University*
[2] *Can Tho University*

competence. Although there have been numerous studies on individual factors, the relationships among instructors' digital competence, feedback, and personalized learning haven't been fully explored. Based on the research gap identified, this study was conducted to answer the following questions: (RQ1) How does instructors' digital competence affect the effectiveness provided to students? (RQ2) How does the instructors' digital competence affect the implementation of personalized learning in university education? (RQ3) Does the students' feedback play a mediating role in the relationship between lecturers' digital competence and personalized learning?

1.1 Problem Statement

Digital revolution has made a remarkable transformation in higher education. The previous studies have focused on the ability of using information technology since 2000s. However, the development of digital learning environment gradually changes not only using technology but also integrating it into teaching. In 2017, Redecker and Punie' study marked the significant alteration of digital competence. From 2016 to 2022, digital transformation boomed at high rate, and teaching online became a global issue. This became a decisive factor in teaching quality and learning experience. Hizam et al. (2021) stated the positive effect on the online learning system. In recent years, the studies have confirmed that digital competence have helped instructors access digital resources and innovate teaching approaches (Dang et al., 2024). Besides, student feedback is also considered an important part of online learning. Especially, digital feedback is a useful tool, helping students exchange information in time. Betancur-Chicué and García-Valcárcel Muñoz-Repiso (2023) certified that digital competence involves evaluation and feedback, one of limited factors of instructors at university currently. Artificial intelligence (AI) is a favorable condition for personalized learning development. The components of digital competence such as, digital resources, assessment, and learning support significantly contribute to student learning experience (Luketić & Diković, 2026).

1.2 Research Objective

The study aims to evaluate the role of digital competence in improving student learning experience through digital resources and the ability to use technology. It is essential to understand how instructors' digital competence affects online learning. Next, the study aims to analyze the influence of digital competence on student feedback and personalized learning. Finally, the study aims to support universities in Vietnam to develop digital competence programs, contributing to online teaching improvement and student-centered approach.

1.3 Research Scope

The study only focuses on surveying the relationship between instructors' digital competence and student feedback and personalized learning. The participants are instructors and students at HIU. The content considers three main variables: digital competence independent variable, students feedback and personalized learning (dependent variables), representing educational results affect by instructors' digital competence. The study does not mention other factors, such as learning motivation, learning outcomes, student satisfaction, and institutional issues. The research method applied quantitative approach through the survey. Data were collected in the definite time, and reflected the participants' perception at the timepoint of the survey.

2. Theoretical Foundation

2.1 The Concept of Instructors' Digital Competence

In the context of digital transformation in university education, Digital Competence (DC) is a core factor that determines teaching and learning effectiveness. This concept may be defined in various ways depending on the approach. However, most of the authors agree that DC is not only the ability to use technology but also includes cognitive, pedagogical, and social competencies in a digital environment. It is a dimensional concept, including the capability to use technology, digital knowledge, and the ability of technology in various learning contexts (Ilomäki et al., 2016). This shows that DC is integrative, and it can't be separated into technology skills and pedagogical competence.

In another study, it is the ability to design, implement, and evaluate teaching and learning activities in a digital environment. The DigCompEdu (Digital Competence Framework for Educators) is an international standardized framework for measuring instructors' digital competence, including competence dimensions: (1) professional engagement; (2) digital resources; (3) teaching and learning; (4) evaluation; (5) empowering learners; and (6) facilitating learners' digital competence. Especially, it emphasizes the role of instructors in using technology to personalize learning and provide students with effective feedback (Redecker, 2017). This proves that DC is an essential condition for promoting pedagogical innovation in university education.

Besides, other studies have confirmed that instructors' DC has a close relationship with the effectiveness of online teaching and student engagement. Instefjord and Munthe (2017) stated that instructors with high digital competence could integrate technology into teaching flexibly and creatively, thereby improving student learning experience. However, DC is not a static characteristic, but it is a process of ongoing development, affected by factors such as teaching experience, professional training, and institutional environment (Tondeur et al., 2017).

2.2 Student Feedback in Digital Learning

Feedback is one of the most important factors influencing the students' learning process. Hattie and Timperley (2007) emphasized that feedback could be defined as the information provided to students about their performance to close the gap between the current state and the desired learning goals. Feedback became very flexible in digital classes with technological support. Online learning platforms enabled instructors to provide immediate feedback and personalize each student's experience. This contributed to learning effectiveness and engagement (Nicol & Macfarlane-Dick, 2006). Feedback could be classified into several types: automated, instructor, and peer feedback. Personalized feedback was the strongest influence on students' learning outcomes. Effective feedback was needed to ensure the characteristics such as timeliness, specificity, guidance-oriented content, and suitability to students' needs (Shute, 2008). In a digital environment, Artificial Intelligence (AI) could support accurate feedback and fit each student. Besides, Carless and Boud (2018) added that it was not only a one-way transmission of information, but also an interactive process, and students played an active role in receiving and using feedback to improve their learning. It was important in digital classes, where students were required to have high self-regulation. However, providing students with feedback encountered challenges, including instructors' workload, insufficient digital skills, and limited technology use (Henderson et al.,2019). Therefore, instructors' DC plays an important role in ensuring feedback quality.

2.3 Personalized Learning

According to Pane et al. (2017), Personalized Learning (PL) is one of the outstanding trends in modern education. It is a content-adjusting method, pace, and learning approach to fit

the needs and the capabilities of each student. Also, it is supported by an adaptive learning system, AI, and data analysis. These tools enable instructors to collect and analyze data about students' learning behaviors, thereby offering content and appropriate learning activities (Holmes et al., 2019). As evidence, Walkington (2013) showed that PL could notably improve students' learning outcomes, motivation, and engagement. PL content according to students' preferences could enhance motivation and learning effectiveness. In addition, PL contributed to students' self-study and self-regulation competence, helping them become more proactive and independent learners (Zimmerman, 2002). This is significant for long-life learning. However, PL implementation faces many challenges, such as high technological requirements, data, and instructors' technological capabilities (Holmes et al., 2019). Therefore, their digital competence plays a core role in designing and performing PL activities.

2.4 The Relationship among DC, Feedback, and PL

DC is a foundational factor influencing feedback and PL in university education. Once instructors possess high digital competence, they can use digital tools effectively to provide immediate feedback and design appropriate learning activities with each student. Redecker (2017) confirmed that one of the important elements of digital competence was the capability of using technology to support and evaluate feedback. This indicated the direct relationship between DC and feedback quality in digital classes. Additionally, DC enabled instructors to explore learning data to understand students' needs and characteristics, thereby designing PL activities (Holmes et al., 2019). This contributes to enhancing learning outcomes and students' satisfaction. Some empirical studies have argued that instructors' DC positively affects students' engagement and learning outcomes through improving the quality of feedback and PL (Tondeur et al., 2017). However, this relationship is not always direct, but it can be affected by the mediating factors, such as instructors' attitudes toward technology, institutional support, and infrastructure (Instefjord & Munthe, 2017).

2.5 Research Gaps

Although many studies about DC, feedback, and PL have been explored, some notable gaps still remain. First, most studies focus on students' DC rather than on instructors', while the role of instructors is very pivotal (Tondeur et al., 2017). Second, the studies have explored the factors in isolation rather than building an integrated model to analyze the relationship among DC, feedback, and PL. Finally, the studies are still limited in the Vietnamese setting, leading to a lack of appropriate empirical evidence for the local context. Therefore, this study addresses the gaps by building an integrated model to analyze instructors' DC affecting student feedback and PL in university education.

2.6 Hypotheses

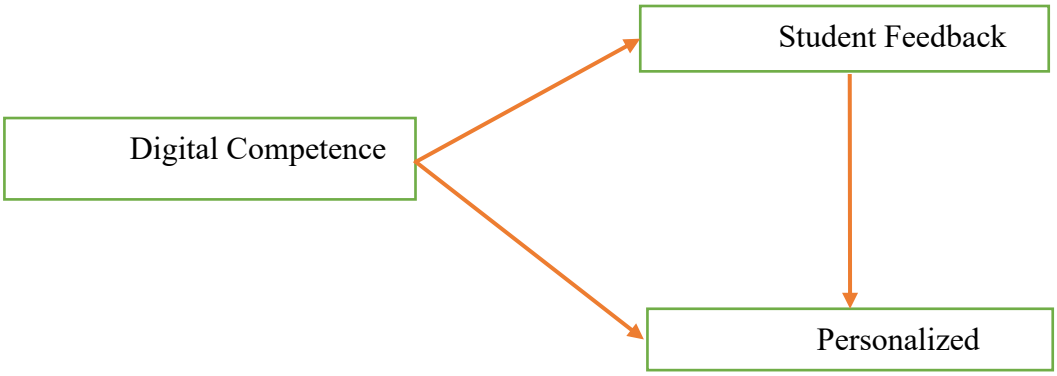
From the above theoretical basis and research gaps, four research hypotheses were proposed, including three direct effects (H1-H3) and a mediating effect (H4).

H1. Instructors' digital competence has a positive effect on student feedback.

H2. Instructors' digital competence has a positive effect on personalized learning.

H3. Student feedback has a positive effect on personalized learning.

H4. Student feedback plays a mediating role between digital competence and personalized learning.



3. Methodology

3.1 Research Design

This study used a quantitative approach to test hypotheses, involving the influence of instructors' DC on feedback and PL in university education. The quantitative approach was selected to measure the research variables as quantitative data and to test causal relationships between variables using statistical techniques (Creswell & Creswell, 2018). In addition, the explanatory research design was also applied to the study. The data were collected via a questionnaire and analyzed using PLS-SEM. This was quite suitable for the studies whose objectives are to test theoretical models and the relationships between latent variables (Hair et al., 2022).

3.2 Research Model

On the theoretical foundation of DigCompEdu (Redecker, 2017), feedback (Hattie & Timperley, 2007), and personalized learning (Pane et al., 2017), the study proposed a three-variable research model, including instructors' DC, student feedback, and PL.

The proposed research model indicates that instructors' digital competence serves as a foundation for improving the quality of feedback and supporting personalized learning. For example, instructors with high digital competence can use technology to provide in-time and appropriate feedback to help students to self-regulate the learning process according to individual needs. At the same time, DC has a direct effect on implementing PL activities without feedback. Besides, students' feedback is also an important mediating mechanism to transform instructors' DC into PL experience. This is quite appropriate with the previous studies, proving that effective feedback is the core factor for improving learning outcomes and student engagement, and instructors' DC can foster interactive quality and technical support (Tondeur et al., 2017).

3.3 Subjects and Sampling Size

The survey participants were students at Hong Bang International University (HIU), enrolling in technology-enhanced courses, including online learning and blended learning. The reasons for selecting this subject were that they directly experienced instructors' DC, received feedback, and engaged in PL activities. Therefore, this was a source of appropriate data to evaluate perceived variables (Hattie & Timperley, 2007). The sampling selection is convenient to ensure the feasibility of data collection. According to Hair et al. (2022), for the PLS-SEM model, the minimum sample size ranged from 150 to 200 observations, increasing reliability. However, the study collected 246 samples to ensure validation.

3.4 Data Collection Instruments

The data were collected through the questionnaire using a 5-point Likert scale, ranging from levels: 1 = Strongly disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly agree. The scales were based on the previous studies to ensure reliability and validity. Particularly, those were the scale of instructors' DC (Redecker, 2017), the scale of student feedback inherited from earning feedback (Hattie & Timperley, 2007; Nicol & Macfarlane-Dick, 2006), and the scale of personalized learning (Pane et al., 2017; Holmes et al., 2019). The use of scales was tested in the previous studies; therefore, they increased the reliability and validity of data collection instruments (Hair et al., 2022).

3.5 Procedure for Data Collection and Analysis

The procedure for collecting data was performed in the following steps. First, the questionnaire was designed based on the scales of previous studies. Second, the pilot test was done to test the transparency and understandability of questions. Based on the results of the pilot test, the questionnaire was adjusted before the main survey. The main data was collected through Google Forms in a defined period. Finally, the data were cleansed to eliminate the irrelevant questions before the analysis performance. This ensured the reliability of data collection (Creswell & Creswell, 2018).

Data was analyzed through SmartPLS with PLS-SEM. The analysis process consisted of measurement assessment and structural model assessment. First, the measurement assessment was tested through the coefficient of Cronbach's Alpha (≥ 0.7), the outer loading (≥ 0.7), Composite Reliability (Rh-c ≥ 0.7), and Average Variance Extracted (AVE ≥ 0.5) to evaluate reliability and convergence. Besides, the discriminant validity was assessed using the Heterotrait–Monotrait ratio (HTMT) index (<0.85) (Hair et al., 2022). Second, the structural model assessment was implemented through the path coefficients and bootstrap to test the statistical significance of hypotheses (Hair et al., 2022).

4. Result Analysis & Discussion

Measurement model assessment and structural model assessment on SmartPLS aim to test reliability and validity. The analysis results are presented in the tables below. These results determine the appropriateness of the model as a solid foundation to discuss the relationships among variables.

Table 1

Outer loadings – Matrix

	DC	PL	SF
DC1	0.857		
DC2	0.859		
DC3	0.847		
DC4	0.822		
DC5	0.841		
PL1		0.880	
PL2		0.865	
PL3		0.904	

PL4		0.907	
PL5		0.887	
SF1			0.861
SF2			0.859
SF3			0.881
SF4			0.863
SF5			0.901

Table 1 indicates the outer loadings of the indicators for three constructs: Digital Competence (DC), Personalized Learning (PL), and Student Feedback (SF). The results illustrate that all indicator loadings exceed the recommended threshold of 0.70. ranging from 0.822 to 0.907. Particularly, the DC construct ranges from 0.822 to 0.859, the PL construct from 0.865 to 0.907, and the SF construct from 0.859 to 0.901. These loadings demonstrate a strong relationship with respective constructs and adequately represent the latent variables. As a result, the measurement model has achieved satisfactory indicator reliability and convergence validity.

Table 2

Construct Reliability and Validity - Overview

	Cronbach's alpha	Composite reliability (rho_a)	Composite reliability (rho_c)	Average variance extracted (AVE)
DC	0.900	0.903	0.926	0.715
PL	0.933	0.935	0.949	0.790
SF	0.922	0.923	0.941	0.762

Table 2 shows the convergent validity of latent variables, including DC, PL, and SF. The value of Cronbach’s alpha was larger than 0.70, fluctuating from 0.900 to 0.933. This reflected the high reliability of scales. Similarly, CR was also over 0.70, reflecting the consistency and stability of scales. Besides, EVA was from 0.715 to 0.790, exceeding 0.50. It was obvious that the observed variables adequately explained the variance of their corresponding latent constructs and satisfied the requirement for convergent validity. This result confirmed that the measurement model reached reliability and validation for the next analysis.

Table 3

Discriminant validity -HTMT Matrix

	DC	PL	SF
DC			

PL	0.841		
SF	0.837	0.835	

Table 3 shows the discriminant validity of concepts of latent variables, including DC, PL, and SF. The HTMT coefficient between PL and DC was 0.861, SF and DC (0.867), and SF and PL (0.875).

Table 4

R-Square Overview

	R-square	R-square adjusted
PL	0.852	0.851
SF	0.783	0.782

Table 4 presents the explanation of the model through R-square overview. The R-square value of PL was 0.852, and the R-square adjusted was 0.851, while the R-square of SF was 0.783, and adjusted 0.782. Generally, it meant that the model explained the dependent variables (PL and SF) quite well.

Table 5

F-Square Overview

	DC	PL	SF
DC		0.213	3.608
PL			
SF		0.476	

Table 5 demonstrates the effect of independent variables on dependent variables. DC has a positive effect on PL with a coefficient of 0.213, a much larger positive effect on SF with a coefficient of 3.608, showing a very strong influence. Meanwhile, PL also affects SF with a coefficient of 0.476, suggesting a moderate influence.

Table 6

Path Coefficients-Matrix

	DC	PL	SF
DC		0.381	0.885
PL			
SF		0.569	

Table 6 illustrates the path coefficients of variables. In the model, the path coefficients were 0.381 (DC→PL), 0.885 (DC→SF), and 0.569 (PL→SF). These coefficients reflected the influencing direction of the relationships in the model.

Analyzing the relationship between variables was to clarify the effect of DC, SF, and PL. The analysis results from the questionnaire are found as follows.

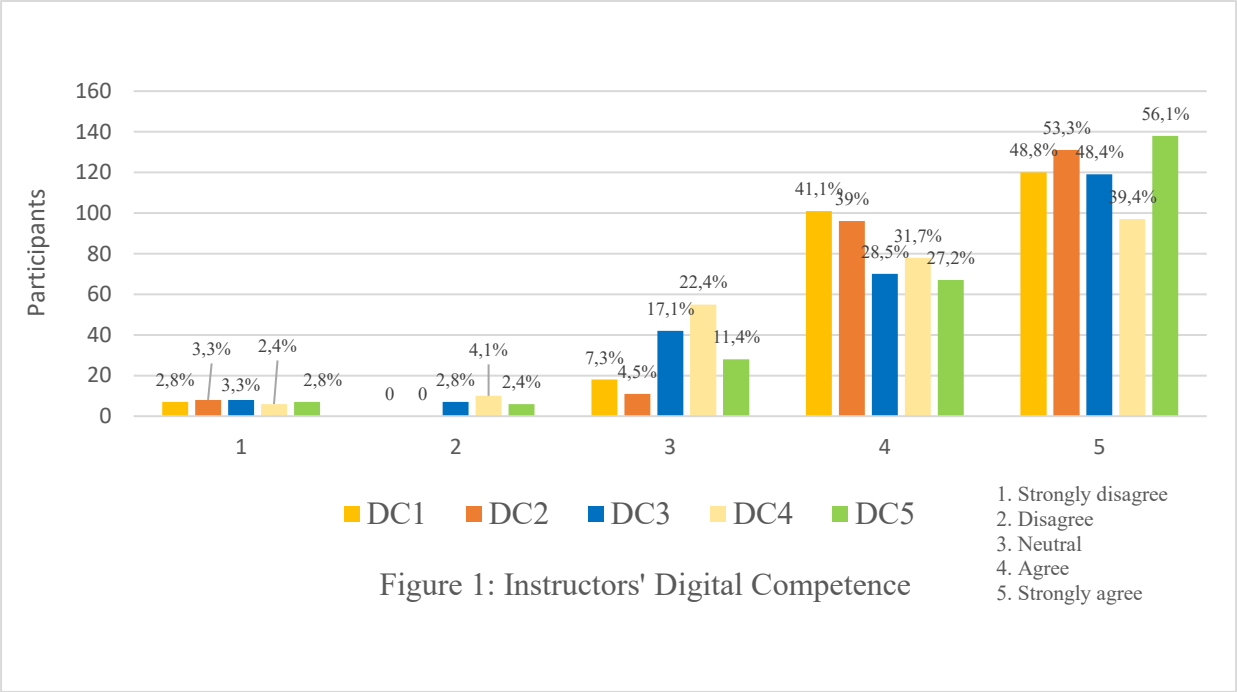


Figure 1: Instructors' Digital Competence

Figure 1 presents instructors' digital competence with five indicators (DC1-DC5). "agreement" and "strong agreement" occupied the highest rate. This proved that instructors were confident about using technology. Particularly, DC2 (selecting digital sources) was the highest, 92,3%; DC1 (effective use of digital tools in teaching) was 89,8%; and DC5 (instructors' support through digital platforms) was (83,3%). While the "Neutral" rate fluctuated from 3,3% (DC1), 2,8% (DC2), 17,1% (DC3 - effective digital classroom organization and management), 28,5% (DC4 - using technology to assess learning outcomes), and 48,4% (DC5). This reflected that some instructors hesitated to use technology. The rate of "disagree" and "strongly disagree" was the lowest in most of the variables, such as DC1 (2,8%), DC2 (3,3%), DC3 (6,1%), DC4 (6,5%), and DC5 (5,2%). Overall, the results proved that instructors' digital competence was highly appreciated in favor of positive agreement, reflecting that instructors were increasingly adapting well to the digital teaching environment and could apply technology in online teaching activities.

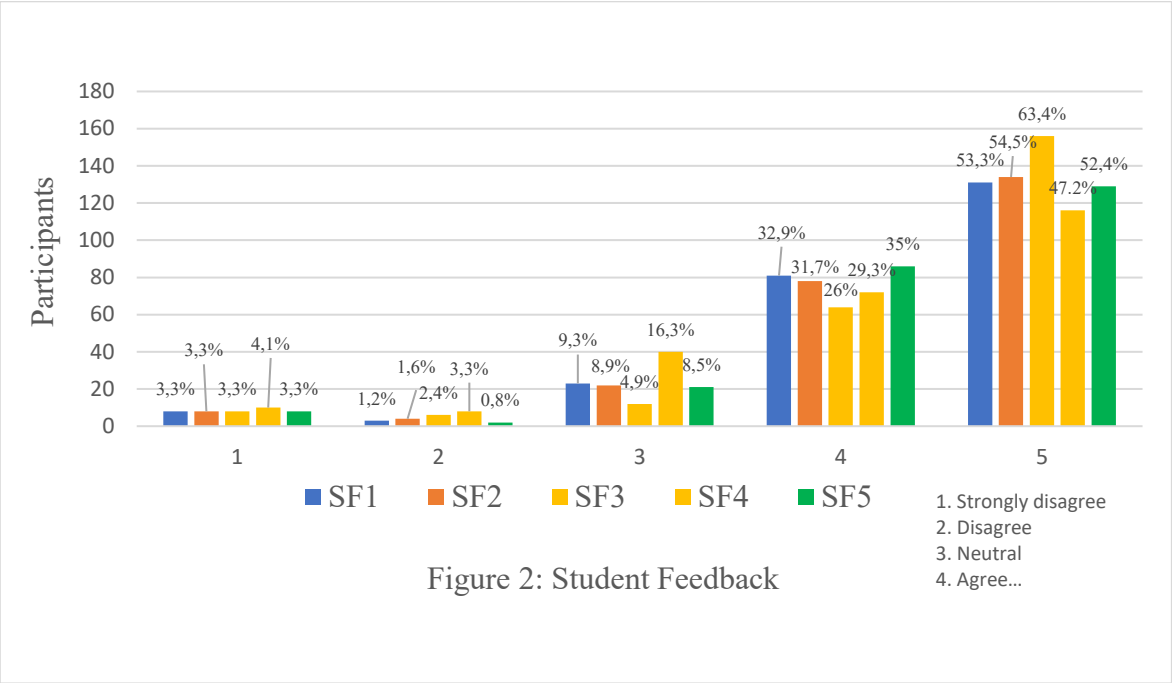

Figure 2: Student Feedback

Figure 2 indicates student feedback in online classrooms through five observed variables (SF1-SF5). Most of participants had positive assessment of feedback at the highest rate of "agree" and "strongly agree", namely 89,4% (SF3 – instructive feedback and learning outcome improvement), 87,4% (SF5 – interaction based on received feedback), 86,2% (SF1 – in-time feedback from instructors), 86,2% (SF2 – feedback helping understand weaknesses and strengths), and 76,5% (SF4 – personalized feedback based on need). In contrast, the rate of "disagree" and "strongly disagree" was very low; SF1 (4,5%), SF2 (4,9%), SF3 (5,7%), SF4 (7,4%), and SF5 (4,1%). Also, the "Neutral" rate was low for variables, ranging from 4,9 to 16,3%. Generally, the results explained that students had positive experience with learning feedback, appreciating the support of the online learning process.

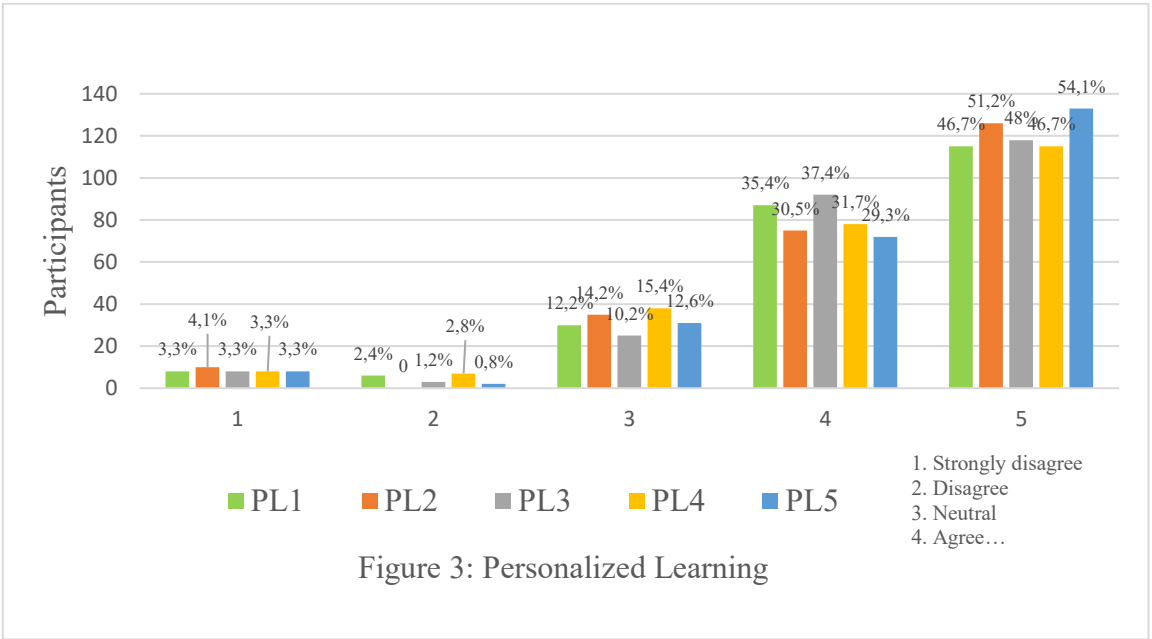

Figure 3: Personalized Learning

Figure 3 illustrates the Personalized Learning (PL1-PL5) framework. According to the results, “agree” and “strongly agree” outnumbered in comparison with other variables, such as 85,4% (PL3 – appropriate materials on the LMS), 83,4% (PL5 – approaching content), 82,1% (PL1 – content appropriateness with individual needs), 81,7% (PL2 – individual learning pace), and 78,4% (PL4 – learning support appropriate with individual competence). These results showed a positive trend in personalized learning, being well-fit with students’ needs and meeting flexibility and individual support in the learning process. The “Neutral” rate fluctuated from 10,2% to 15,4%, reflecting that fewer participants had a clear decision in doing the survey. The very low rates for “disagree” and “strongly disagree” occurred for most of the variables under 5%. There were fewer negative ideas for PL. In overview, the results demonstrated the role of personalized learning in enhancing the online learning experience.

5. Conclusion

In conclusion, there is a positive effect of digital competence on feedback and personalized learning. Instructors’ digital competence consists of selecting digital sources, using digital tools in teaching, providing technical support through digital platforms, organizing and managing effective digital classrooms, and assessing learning outcomes through technology use. Instructors tend to adapt well to the digital teaching environment and apply technology in online teaching activities. The influencing factors are found through the following items. First, HIU instructors’ digital competence positively affects feedback. When instructors have high digital competence, they can provide more rapid and diverse feedback. The forms of feedback include instructive feedback and learning outcome improvement, interaction based on received feedback, in-time feedback from HIU instructors, feedback helping understand weaknesses and strengths, and personalized feedback based on need. Second, digital competence directly affects personalized learning thanks to technology support in designing content and a learning path for each student, selecting appropriate materials on the LMS, approaching content, ensuring content appropriateness with individual needs, maintaining individual learning pace, and providing learning support appropriate to individual competence. Third, HIU students’ feedback has a powerful effect on personalized learning because the quality of feedback helps them adjust the learning process based on individual needs. Finally, HIU student feedback plays a mediating role in the relationship between digital competence and personalized learning. From the above results, the recommendations of the study are that HIU in particular and universities in general should build digital competence training programs and professional development for instructors.

#81 THE TEACHER AS A FACILITATOR IN CULTIVATING ENGLISH-RICH HOME ENVIRONMENTS: A PARENTAL COACHING APPROACH FOR PRIMARY EDUCATION

Tham Truong Thi [1], Thanh Phan Thi [2]

Abstract

This paper introduces an action research that helped primary students learn English at home with their parents' involvement. In this research, the teacher played a role as a facilitator in coaching the parents to become their children's partners in learning English at home. This bridged the gap between the classroom and home environment for primary students in the context of teaching and learning English as a second language. The research was conducted to investigate how the teacher's guidance to parents and their support would affect students' development in learning English. There were 21 students and their parents in her class participating in the research for four weeks. The teacher used a digital platform (Zalo group) to give guidance and collect data. The teacher used three data collection methods: classroom observation, portfolio and semi-structured interview to ensure objectivity. The preliminary results of the experiment revealed that when the teacher was involved in guiding parents, the home environment became a supportive second-language environment for the child, and this was beneficial for the child's confidence level when they used the target language. It was shown that the teacher-facilitated parental coaching model is an applicable solution for the long-term development of English in the Vietnamese primary school context.

***Keywords*:** English-rich home, teacher as a facilitator, coaching, supporting, primary learners' English development

1. Introduction

The transformation of teaching and learning English from a foreign language to a second language in the Vietnamese education system is considered an innovative step of the globalized human resource development policy in the period of 2025-20245. In the era of rapidly growing digital technology, human resources with English or any foreign language are not prefered anymore. The ability to speak a foreign language is a compulsory criterion in the global labour market.

In the resolution 71-NQ/TW on August 22nd, 2025 about educational and training development, the Politburo focuses on enhancing teachers' and students' English level, step by step, to turn out English as a second language. It leads to an approval through a decision 2371/QĐ-TTg, which was approved "Teaching English as a second language in school from 2025 to 2035, a vision to 2045". To achieve the targets, besides the changes in curriculum programs and the improvement in training teachers at school, English should not be taught only at school, but everywhere in life.

The Research Gap

At present, most students in public primary schools in Ho Chi Minh City are taught English in 3-4 periods per week. This time is not enough for them to practice and immerse to

[1] *Tham Truong Thi, MA., Faculty of Foreign Languages, University of Labour and Social Affairs, Ho Chi Minh City, Vietnam; Email: thamtt@ldxh.edu.vn*
[2] *MA., Faculty of Foreign Languages, University of Labour and Social Affairs, Ho Chi Minh City, Vietnam*

English in addition to classes with a large number of students. After school, students often take part in extra English classes. These classes usually last four hours per week. When they come home, they do not have an environment to practice English because their parents think teaching and learning English is the teacher's responsibility. This causes a language vacuum after school. According to Spolsky (2004), on the theory of Language Policy, one of the domains that should be extremely important for learning language would be family; yet, many Vietnamese families appear to be inactive, which could be attributed to the phenomenon described by Hoover-Dempsey & Sandler (1997) as the "lack of parental self-efficacy". Moreover, many parents are afraid of supporting their child since they are not good at English pronunciation. However, according to Epstein (2011), on school-family partnerships, it is suggested that reinforcing learning at home is significantly pivotal for students to gain success.

To bridge this gap, the coaching role of the teacher should be promoted. Parents are those who manage their children's home time, yet teachers are those who provide the pedagogical methods to help them teach their children.

Research Aim

This action research is conducted with the aim of investigating the effectiveness of teachers' parental coaching. By employing a digital communication platform via Zalo group, the teacher can deliver guidance to instruct parents to create a home-rich English environment, as a natural part of daily life rather than a stressful academic task (Krashen, 1985).

Research Questions

1. How can a teacher coach parents to create an English-rich environment at home for primary students?
2. To what extent does the teacher-facilitated coaching model influence parents' self-efficacy and level of engagement in supporting their children?
3. How does parental support affect students' level of confidence and lesson retention?

2. Literature Review

2.1. Second language acquisition and Language environment

According to Krashen's input hypothesis (1985), human beings acquire a language through understanding comprehensible input. It brings special importance to children who learn a language better through language immersion. Moreover, Lightbown and Spada (2013) emphasize that the length of time of language exposure plays a decisive factor to young learners' success.

Besides that, Sénéchal and LeFevre (2002) developed the home literacy model to prove the approach of unofficial language activities such as listening to music and reading stories at home significantly supports young learners' language acquisition ability at school. An outstanding demonstration from Hart and Risley (1995) shows that a child's language ability doesn't depend on their innate ability, but rather is based on their language exposure in their early family environment. In the second language acquisition context, it is insisted that the family environment is an important extra-class after school.

2.2. Parental participation and Social interaction theory

The zone of proximal development (ZPD) (Vygotsky, 1978) is an important concept in socio-cultural theory. According to the theory, he states that social interaction plays an indispensable part in children' s learning process, influenced by diverse cultures. Having the

same point of view as Piaget, Vygotsky believes children are the most active learners of all ages. ZPD is defined as the zone of potential development, referring to the gap between the realistic development level identified by independent problem solving and the potential development level identified by solving problems when they are instructed by the older or associated with better partners. In this case, parents are more knowledgeable, providing essential scaffolding for children to practice English at home.

In the six types of school-family cooperation, Epstein (2011) identifies that learning at home is a key element. In contrast, parents only participate in their children's learning process when they have sufficient self-efficacy. Along with Epstein (2011), Bandura (1997) shares the same opinion. An action can be taken only when the parents anticipate positive results. Vietnamese parents tend to underestimate their English proficiency.

Based on the theory of scaffolding (Wood, Bruner and Ross, 1976), parents are not required to teach grammar or be another teacher; they are asked to be a scaffolding to step by step elicit and motivate children to study. Therefore, teachers must coach parents to encourage their confidence.

2.3. Teacher as a facilitator

In modern times, the transition from a teacher to a parental instructor means simplifying pedagogical skills so that parents can easily guide their children. Teachers are not the only source of knowledge any more. According to the facilitation theory (Rogers, 1969), a facilitator must believe in others' capacity to learn and to do well. In fact, the role of the teacher is still crucial while parental coaching is a step of the scaffolding model. However, to make it successful, the teacher must ensure to create four factors: confidence, competence, connection and cognition. Traditionally, parents play a role of involvement; nevertheless, this research moves it to empower parents' self-efficacy.

2.4. Digital technology – The bridge connecting teachers and parents

In the context of rapid digital technology development, the relationship between the school and parents needs to be digitalized continually. Parents are not only "supervisors", but also digital partners, corresponding with the teachers in managing, orienting, supporting and evaluating their children's learning process through digital platforms. As Goodall (2016) highlights, technology-mediated engagement successfully transforms parents from external observers into active co-educators. Furthermore, empirical findings by Kuusimäki et al. (2019) confirm that the appropriate implementation of digital communication channels fosters sustained home-school dialogue, effectively integrating parental voices into institutional practices and expanding collaborative learning opportunities.

3. Methodology

3.1 Research design

This action research adopts a qualitative action research design, following the process of planning, acting, observing and reflecting (Hinchey, 2008). The purpose of this research is to improve and enrich the English home environment by coordinating and coaching parents.

The research context is conducted in the author's English classes from grade 1 to grade 5, involving 21 students.

The research objectives and procedures were clearly introduced to all of the participants. By employing a qualitative triangulated framework, namely, observation, Journal analysis and semi-structured interview, I analyzed the authentic data to explore the impact of

teacher-led parental coaching on young students' English acquisition. Additionally, concrete implications were given to help teachers of English improve the quality of their home-school partnerships.

3.2 Participants

There are three groups of participants involved in this action research:

- One teacher (the author) played the role of facilitator and researcher, designing micro-scaffolding exercises, giving directed exercises and observing the process.
- 21 parents acted as home-coaches and followed the teacher's guidance to remind, encourage and interact with their child to help do English exercises at home.
- 21 students from grades 1 to 5 take part in the learning process both in class and at home.

3.3 Data collection

According to Dahlberg & McCaig (2010), practitioner-researchers conduct qualitative research in order to seek in-depth information related to the issue. To raise the reliability and validity of the data, the data was collected around a qualitative triangulation framework utilizing three distinct instruments: observation notes, a portfolio, and semi-structured interviews.

Observation was the first method used in the research to capture real-time classroom behaviours. Dahlberg & McCaig (2010) state that open-type observation is often employed within school settings of action research to analyze children's actions and behaviors. And Finch (2005) further discusses in his paper that observation allows teachers to reflect on the classroom performance. Consequently, observation notes were maintained.

The second was a digital portfolio. The researcher collected and documented qualitative artifacts, including screenshots of parents' text responses, photos and feedback on Zalo groups after delivering the instructions.

The final instrument was semi-structured interviews conducted with 7 selected parents at the end of the research process. Semi-structured interviews are useful for researchers to elicit interviewees' perceptions (Dahlberg & McCaig, 2010).

3.4 Research data and data analyses

Data analysis is a critical phase that transforms raw qualitative evidence into meaningful academic insights. In this research, the data includes transcripts of interviews, notes from classroom observation and a digital portfolio. According to Dahlberg and McCaig (2010), qualitative data analysis follows a fundamental sequence from collecting and coding to categorizing, interpreting, and reporting.

To analyze the data with academic rigor, this study also adopted the systematic thematic analysis framework established by Braun and Clarke (2006), utilizing its phases to identify themes. Simultaneously, the practical, hands-on coding techniques recommended by Hinchey (2008) for practitioner-researchers were integrated into the process.

The integration of these three methodological frameworks was executed through the following structured steps:

Data familiarization and transcription (Dahlberg & McCaig, 2010; Braun & Clarke, 2006): The tape-recorded data from the semi-structured parent interviews were transcribed

verbatim. The researcher repeatedly read the transcripts, classroom observation notes, and Zalo portfolio entries to gain an immersive, in-depth understanding of the text.

Initial code generation and color-coding (Hinchey, 2008; Braun & Clarke, 2006): Raw data segments were assigned initial codes to capture meaningful semantic features. To visually manage and distinguish different kinds of information at this stage, the study employed various practical techniques suggested by Hinchey (2008), such as using distinct colors, symbols, and highlighters. For instance, statements reflecting parental language anxiety were highlighted in one color, while instances of student lesson retention during observations were marked in another. This provided quick and easy visual access to the codes.

Searching and categorizing for themes (Dahlberg & McCaig, 2010; Braun & Clarke, 2006): In line with Dahlberg and McCaig's (2010) phase of categorization and Braun and Clarke's (2006) theme generation, the codes were collated into broader conceptual patterns.

Defining and naming core themes: Three major academic themes directly address the research questions:

- Theme 1: Teacher-led coaching strategies and parental conceptual understanding
- Theme 2: Psychological and behavioral shifts in parental self-efficacy and attitudes across age groups
- Theme 3: Student cognitive outcomes and systemic obstacles to model sustainability

Interpreting and reporting (Dahlberg & McCaig, 2010; Braun & Clarke, 2006): Following the final steps outlined by Dahlberg and McCaig (2010), the analysis was reported by combining practical findings supported by direct quotes from participants to maintain the qualitative trustworthiness of the action research.

4. Results

4.1 Teacher-led coaching strategies and parental conceptual understanding

The first theme of the implementation of teacher-led coaching strategies and how they deliver the messages and show insight into the receiver's perceptions. The data from the Zalo digital portfolio and interview transcripts demonstrated a significant shift in parental pedagogical awareness.

Before the research, the parents just reminded their children to complete their homework without any instructions. Since the teacher introduced explicit and micro-scaffolding instructions to them, the instructions have changed their approach. As shared in an interview:

" *I feel more confident and sometimes I play a game with my child when the teacher instructs the parents."*

This behavioural improvement proves that parental engagement needs clear instructions from teachers. This finding aligns with Rogers (1969) that the educators' role should change from a transmitter of knowledge to a facilitator creating a supportive learning system.

Moreover, portfolio data from the Zalo digital platform revealed a strong correlation between instructional delivery and parent responsiveness: parents who actively supported their children consistently interacted with, "liked," or replied to the teacher's coaching

messages, whereas non-engaged parents rarely reacted. This pattern supports the theoretical premise that technology-mediated communication optimizes home-school partnerships when digital inputs are concise, actionable, and conceptually accessible to non-educators (Kraft & Rogers, 2015; York et al., 2019).

4.2 Psychological and behavioral shifts in parental self-efficacy and attitudes across age groups

According to observation notes and interviews, the coaching model shows that the role of parents changes based on the students' level.

A group of grades 1 and 2: This group had the largest number of parents who often supported them with homework. At this age, students still need clear and detailed instructions from teachers or parents because they lack autonomous learning strategies.

A group of grades 3 and 4: In this intermediate group, most parents move to the role of reminding their children to do homework. Parents provided targeted guidance whenever their children encountered questions.

A group of grade 5: At this senior primary stage, children have formed study habits of independence, even whether their parents remind them to do homework or not. However, by observing them, the researcher realized that the students who finished their coached home assignments were more confident during lessons than those who didn't.

The adjusted parental support according to age proves the scaffolding concept of Wood, Bruner and Poss (1976) and is rooted in Vygotsky's (1978) Zone of Proximal Development. As the learner's competence grows, the parental coach gradually moves from external support to encourage the learner's autonomy.

This finding also supports the perception of Lightbown and Spada (2013) regarding age-related factors in second language acquisition (SLA). Younger learners need more consistent support than older ones in primary school.

4.3 Student cognitive outcomes and systemic obstacles to model sustainability

4.3.1 Impact on Student Lesson Retention and Confidence

Based on the data collection, it can be seen clearly that there are strong discrepancies among students with parental support, those with less support and a group with hardly any support.

The group with entire parental support: In this group, students were reminded to do exercises, directed to review and check after finishing their homework by their parents. The dominant students are Cherry, Xuka, Sunny, and Quyen, who show exceptional cognitive retention of previous lesson content and high confidence in responding to the teacher's questions. Similarly, other students, including Mimi, Hanna and Win, went to class with confidence and superior vocabulary recall ability.

The group with less parental support: In this group, parents just reminded the students generally to do their homework, but gave no scaffolding instructions. As a result, these students (Khoa, Quoc Quan, Minh Quan and An Nhien) just occasionally did homework and revised lessons, leading to inconsistent classroom participation.

The group with no parental support: In this group, the students often felt worried and unconfident, particularly during the initial moments of entering the classroom or when required to check their previous lessons.

These discrepancies evidence the emotional filtering hypothesis (Krashen, 1982). Guided parental support at home creates a psychologically safe environment, minimizing children's anxiety and fear and optimizing language acquisition. These differences also reflect the findings of Hart and Risley (1995) on the profound impact of the early home language environment on learning pathways.

4.3.2 Systemic and Situational Barriers

Through evaluating the results of note-taking and interviews, the paper has identified some main reasons affecting the effectiveness of the model: workplace exhaustion, school workload and parental linguistic anxiety.

The obstacles from work: " I am so tired after work, I just want to let my hair down so I forget to remind my child", said Truc Anh's mom and " I often finish my work late", said mother Thao and Rio's mom. Both of them really want to learn side by side with their children; however, they were attracted by their heavy workload.

"My children's school homework is too much, and they don't have enough time to do their homework in your English extra class", another said.

"I don't know English, so I just remind him to finish his homework", said Phuc's mom.

These empirical findings align strongly with literature on primary EFL education and family dynamics in Vietnam (Hamid & Nguyen, 2016), which underscores that demanding occupational pressures coupled with intensive primary school workloads construct formidable structural barriers for busy parents. Consequently, even though the parental coach model brings positive effects on learners' cognition and emotion when learning English as a second language, it depends significantly on teachers' ability to provide flexible, time-saving and linguistically understandable micro-tasks that maximize parental support.

5. Discussion

5.1 Scaffolding and parents' psychological barriers

The empirical findings indicate that the effectiveness of the model varies depending on the level of parental involvement: active instructional scaffolding, passive behavioural monitoring and complete non-engagement.

According to Wood and associates (1976), accompanying their children in learning at an early age is strongly recommended for parents. When there is only a generic reminder, many students seem distracted. They might struggle with task ambiguity, or sometimes they neglect assignments due to the absence of parental verification.

About 50 percent of parents were not involved in their children's learning process or with a generic reminder. The reasons may not come from a lack of care, but they felt unconfident, low self-efficacy and under pressure of wrong pronunciation or encountered the barrier of pedagogical methods (Bandura, 1997).

The case of student Cherry, who was immersed in full parental support, is a clear demonstration of implementing the right process of distributed scaffolding. This association helps maximize the zone of proximal development (ZPD) according to Vygotsky (1978). Hence, students can actively practice English at home.

5.2 Students' performance and psychology

Observational data indicate that home-school mediation significantly shapes students' psychological readiness in class.

The students who had well-prepared homework came to class with high confidence and active engagement. According to Krashen (1982), when the anxiety diminishes, the affective filter is low. Therefore, children are ready to acquire a second language most successfully and productively.

In contrast, the failure to complete home assignments before going to class creates anxiety for children. It leads to a high affective filter which restricts their language acquisition with timidity and inactivity.

5.3 Learner autonomy

Based on the researcher's observation, the data reflect a linear progression of primary students' autonomy. Most students in grades 1-2 need clear instructions from parents; those in grades 3-4 can do homework themselves and ask their parents if necessary, while those in grade 5 are likely independent. This progress requires flexibility of teachers as a facilitator. In early grades, teachers should coach parents with clear and detailed instructions. Whistle in older grades, teachers should focus on designing learning materials with a student-centered approach, now that they are aware of their responsibilities.

5.4 Practical obstacles

Qualitative interview data reflect the fact that discrepancies in parental engagement are primarily driven by systematic and situational factors.

Because of the dual burden of heavy daily workloads from work and home chores in our modern society, parents sometimes forget to remind their children to do homework. Moreover, besides English homework from the extra English classes, children have to complete the heavy workload of school assignments. Thus, they are not able to manage their time to complete all of them. Additionally, the time balance between learning and relaxing is considered more important to some parents than their high demands on children's learning.

The empirical finding indicates that conventional and time-consuming pedagogical directions may fail in some cases of busy parents. Parents can not change their work schedule; hence, teachers' responsibility is to adapt and streamline instructional delivery methods.

5.5 Recommendations

Roles of Teachers

To balance groups of parents, it is recommended to create short videos that parents can play for children to follow, instead of only written instructions. Making videos can take more effort from teachers but it is worth dedicating.

Teachers can also install automatic reminder functions on Zalo groups with positive encouragement to solve the problem of forgetfulness. Rather than reminding parents in groups, teachers send messages to each busy parent.

Roles of parents

After being instructed by teachers, parents can build an enriched English environment. Parents must be the ones to set up and manage children's learning time, following 3-step scaffolding: Remind (remind children it is time to do homework)-Activate (play videos or instruct if necessary)-Check (check children's answer and reward).

In response to excessive homework, parents often utilize time-budgeting assistance as a crucial scaffolding tool to alleviate psychological distress and minimize student burnout.

Roles of students

Instead of waiting for their parents' instructions, children must learn how to study autonomously to finish their work. Teachers and parents allow them to raise questions in case they address the struggles.

Students are directed to inform teachers initially and ask for help if they forget to do homework to reduce their anxiety and release stress right after that. This will lower their affective filter and keep confidence.

6. Conclusion

This action research was conducted to investigate the effectiveness of parental coaching by teachers as a facilitator. The practitioner-researcher aims to help primary students have chances to practice English in a rich-English home environment. Through data collection methods: observations, portfolio and semi-interview, the research comes to conclusions as follows:

- The research confirms that the act of parental intervening forms students' behaviors and emotions in class. When parents spend enough time supporting students, they go to class with high confidence and acquire the knowledge superior to others in the next lesson. In contrast, those who are not instructed feel worried.

- The model observes a natural progression in children's self-learning abilities. Grades 1-2 rely entirely on external support (currently, 50% of parents provide both reminders and guidance effectively); grades 3-4 begin to work independently and only ask for help when encountering difficulties; while grade 5 students have reached a state of complete self-reliance without needing frequent reminders from parents.

- The breakdown in the support process doesn't stem from a lack of cooperation, but rather from the double pressure of time constraints: parents are busy with overtime work, and students are overwhelmed by the volume of schoolwork.

Understanding parents' barriers and students' anxieties is the key for teachers to create a humane, effective and sustainable educational environment.

Bionote

Truong Thi Tham and Phan Thi Thanh are English lecturers at the University of Labour and Social Affairs, Campus 2, Ho Chi Minh City. Both of them have been working as lecturers for over ten years. During their teaching time, they have had numerous opportunities to approach innovative teaching and learning methods through the papers of experienced researchers from around the world. They have also written research papers for their university's workshops, in an attempt to find the best way to teach their students.

Appendices

Appendix A: A SAMPLE OF THE TEACHER'S INSTRUCTION

Appendix B : QUESTIONS FOR INTERVIEWING PARENTS

1. How do you usually remind or support your child's homework with instructions from the teacher? (Do you just remind them to do it themselves, or do you sit down and review it with them?)
2. What do you often do when your child doesn't understand a part? (Do you proactively guide and explain it to them, or tell them to ask the teacher the next day?)
3. Can you share any difficulties you often face in reminding your child to do their homework regarding time or work schedules?

4. How much homework do you find in your child's current workload (in the regular curriculum)? Does this workload significantly affect the time your child spends practicing English at home?
5. Are there any barriers in terms of English proficiency or methods that make you feel anxious or hesitant when helping your child?
6. How is your child on days when they complete all their homework before going to class?
7. Conversely, on days they haven't finished homework, do they show any signs of anxiety or share anything with you before going to school?
8. To make supporting your child at home easier, more convenient, and less time-consuming for busy parents, how do you think teachers should change their assignment methods or instruction approaches?
9. Do you have any suggestions for reminder methods (e.g., automated messages, short instructional videos under 1 minute, etc.) to help you avoid forgetting your child's homework schedule?

Appendix C: A SAMPLE OF AN OBSERVATION IN GRADES 1-2

After the teacher assigned homework to the students and gave instructions to the parents, the following happened in the class the next day:

- Cherry, Win, Hana, Mimi: Their mothers reminded them, helped them with their homework and checked their work. These students were very happy and confident when the teacher checked their work, submitting their assignments loudly and clearly. When starting a new lesson, they were also very confident and enthusiastic and learned the new lesson better.

- Khoa: His mother reminded him to do his homework, but he didn't finish it because she didn't give him instructions. He seemed worried when the teacher asked about his homework.

- Quân: His mother went to work and forgot to remind him, and he forgot to do his homework. He said that he also had lots of homework from school. He seemed worried when the teacher asked about his homework.

- Trúc Anh, Nami: Their mothers forgot to remind them to do their homework. These students seemed worried when the teacher asked about their homework.

#82 AI-ASSISTED ESL LEARNING AND STUDENT MOTIVATION: CHALLENGES AND OPPORTUNITIES FOR SOFTWARE ENGINEERING EDUCATION

Do Duc Bich Ngan[42]

Abstract

In Vietnam's software engineering (SE) industry, English proficiency plays an important role in career development and in communicating with international clients. However, for many students in the major, English remains a common obstacle to graduation and future employment. In this context, the rapid growth of Artificial Intelligence (AI) has brought both opportunities and challenges. On the one hand, AI provides valuable support for English learning and academic work. On the other hand, it may reduce students' motivation to learn independently, which leads to possible overreliance on AI tools.

The aim of this paper is to investigate the effects of AI-assisted tools on learning motivation and autonomy of software engineering (SE) students at HUFLIT University. The study mainly employs a quantitative approach, supplemented by a number of open-ended questions to gain deep insights into SE students concerning their learning attitudes and their perceptions of using AI tools for language learning.

While AI tools may develop knowledge, convenience, confidence, and access to learning support, high dependence on AI could reduce students' initiatives and independent thinking in the learning process. Based on the results, the study proposes several AI-assisted learning strategies to support students' motivation, proactiveness, and self-study skills in English learning.

Keywords: AI-assisted language learning (AIALL), computer-based language learning (CALL), English as a second language (ESL), learning motivation, software engineering (SE) education, learner autonomy, interactive AI solutions

1. Introduction

In Vietnam today, English has become a strategic competence that determines career development, as reflected in the Government's Decision No. 2371/QĐ-TTg (2025), which approves the project of "making English a second language in schools for the 2025–2035 period, with a vision to 2045". Particularly, in the field of Science and Technology, students often work with English technical materials and resources. English proficiency enables students to approach up-to-date knowledge. Furthermore, for SE technicians, this not only reduces costs and speeds up project timelines but also helps them stay competitive in the global software market.

At present, there is a mismatch between students' English learning orientations and practical demands. Most software engineering (SE) students tend to focus much on developing

[42] *Information Technology, HUFLIT University, Ho Chi Minh, Vietnam; nganddb@huflit.edu.vn*

technical expertise, whereas underestimating the importance of English learning. As a consequence, some students in this major (SE) are not able to graduate on time or to be well-prepared for their future career. This is not due to a lack of professional competence but because they fail to meet even basic English proficiency (Hong Mai, 2026). In reality, capable Vietnamese software programmers with limited English competence are often restricted to purely technical roles, not being able to take on higher-level responsibilities such as senior developer or manager. Consequently, many IT companies in Vietnam nowadays require their staff not only technical skills but also English proficiency to collaborate directly with international clients for their projects.

Traditionally, English learning has relied mainly on teachers' instructions and later computer-assisted language learning (CALL), which often provides limited personalization or lack of human-like interactions. Recently, AI-assisted language learning tools (AIALL) have marked a significant move, which can personalize students' learning and promote their learning English. At present, several Asian countries, such as China and South Korea have implemented AI-driven platforms with adaptive learning systems and conversational agents, to support English learning through personalized feedback and interaction (Miao et al., 2021, pp. 28–30).

Even though the integration of AI-assisted tools in English learning is constantly increasing, the understanding of how SE students actually use these tools and how such use influences their motivation and autonomy in English learning is still limited. It remains unclear what benefits and challenges they encounter. Currently, in the context of Vietnamese education, while several studies have examined learner autonomy, motivation, and English proficiency among non-English major students (Ho, 2018; Le & Nguyen, 2022; Nguyen & Nguyen, 2020) and some have explored the general benefits of AI tools in English learning (Pham & Pham, 2024; Hoang et al., 2024), limited research has investigated how AI specifically influences the motivation and autonomy of SE students in English learning.

Therefore, this study aims to investigate ESL learning supported by AI-assisted tools among SE students by examining their perceptions, usage experiences, and the effect of AI tools on their learning motivation and autonomy. Below are the research questions of the paper:

1. What are SE students' perceptions of AI-assisted tools in English learning?
2. How do SE students use AI tools for ESL learning, and what benefits and challenges do they experience?
3. How does the integration of AI-assisted language learning tools affect SE students' motivation and autonomy?

Based on the research questions and objectives, two hypotheses are proposed as follows:
Hypothesis 1. SE students' regular interaction with AI-assisted English learning tools is associated with high levels of English learning motivation.

Hypothesis 2. SE students' perceptions of the benefits against the drawbacks of AI tools affect their attitudes toward using AI for learning English.

The study shows an exploratory understanding of AI-assisted ESL learning, focusing on SE students who frequently interact with technology more often. This also helps offer more practical insights and recommendations for teachers and students in integrating AI into English

learning practices. In terms of scope and delimitation, the study only deals with SE students and does not aim to represent students from other majors. It focuses on students' perceptions and experiences rather than objectively measuring English proficiency improvement. In addition, the study examines AI as a language-learning support tool and does not investigate AI applications beyond ESL learning contexts.

2. Literature Review

2.1. Artificial Intelligence (AI) in ESL Learning

AI tools have gradually changed English language learning, shifting from CALL to AIALL. This suggests the new attention to individualized and interactive learning. These new tools are considered to aid in the acquisition of language through personalization, automated feedback, and multi-modal interactions (Selvi et al., 2025). They are currently used in ESL learning contexts, including AI Chatbots (ChatGPT, Google Gemini, …), Automated Writing Evaluation tools (AWEs) (Grammarly, Quillbot, …), and Intelligent Tutoring Systems (ITS). These tools have various applications: Chatbots facilitate active communication and the ability to utilize language in real-world settings (Fryer & Carpenter, 2006; Kohnke et al., 2023), AWEs can also offer instantaneous feedback to learners that leads to better writing accuracy (Stevenson & Phakiti, 2019), and ITS offers personalized instruction that adapts to the abilities of the learner (Holmes et al., 2019). They can individualize content to match the learner's skill level, allow learners to receive instant feedback, and supply various inputs such as text, sound, and visuals, which give learners control over how they learn English, thus providing a more dynamic learning environment. Also, although learning effectiveness is reliant on the extent to which learners critically engage with the output of the tools, studies show that AI tools contribute to an improvement in the quality of learners' writing and encourage sustained practice (Selvi et al., 2025).

Additionally, AI tools function in language learning as writing aids, conversation partners, and personalized tutors which not only promote the learning of English among students but also foster learner autonomy by providing students with the ability to take control over their learning.

As for SE students, English is considered important because they need to access technical documents and interact globally to advance their career opportunities. AI-assisted tools are highly relevant and useful in this context, as they enable learners to engage in interactive practice, receive quick feedback, and develop communication skills beyond traditional classrooms (Huang et al., 2021).

In sum, the tools have gradually proved to be a crucial component of modern ESL learning. However, the extent to which the tools can help learners depends mainly on how learners use them, highlighting the need to examine their impact on motivation and autonomy.

2.2. AI and Learner Motivation and Autonomy

AI tools can influence the learning motivation of students in different ways (Hussain et al., 2025). Obviously, educational environments equipped with AI-assisted tools can bring interactive, personalized, and engaging experiences to learners, so they can enhance learners' motivation. The tools include conversational agents that allow learners to practice communication in low-pressure settings. Moreover, features such as instant feedback and relevant support can strengthen learners' sense of competence. Hence, it is clear that the use of AI tools in language learning may increase

students' willingness to participate and sustain engagement (Fryer & Carpenter, 2006; Huang et al., 2022).

However, AI tools do not increase learners' motivation automatically (Guzmán Alvarado et al., 2025). It depends largely on how they are used and perceived, learners' goals, learning strategies, and level of engagement. If students mostly use AI tools for completing their tasks rather than learning, they may have a limited impact on motivation (Badarudin et al., 2025). Hence, when evaluating AI's role in motivation, it is necessary to consider not only what an AI tool can do but also how learners actually use and respond to it.

According to Liu (2015), motivation and learner autonomy are closely linked in second language learning. It means that motivated learners are more likely to act autonomously, which enhances learners' motivation. Also, Ryan & Deci (2000) point out that learners are more motivated when they can take control of themselves and feel more competent, which fosters intrinsic motivation and deeper engagement. It can be derived that a student who feels autonomous but incompetent may feel unconfident or lack motivation. As a result, students can advance their language proficiency in a way that promotes their autonomy and competence, which in turn strengthens their motivation. Furthermore, AI-assisted learning environments can support the development of autonomy by enabling learners to set goals, monitor progress, and engage in self-directed learning (Yang, 2026). Tools such as chatbots and writing assistants allow learners to practice continuously without constant teacher intervention, encouraging greater responsibility for their learning.

In the Vietnamese context, some empirical studies consistently emphasize the importance of learner autonomy in improving English proficiency, particularly among non-English major students. Ho (2018) found that higher levels of autonomy are associated with better learning outcomes (scores) in English language courses. Similarly, Mohebbi (2024) highlights the need to promote autonomy to help learners adapt to AI-supported learning environments.

In conclusion, AI has the potential to improve both learner motivation and learning autonomy; however, its impact depends on how learners engage with it. This suggests that integrating AI in ESL learning involves not only the use of AI tools but also guidance that encourages learners to study purposefully and independently**.**

2.3. Opportunities and Challenges of AI in ESL Learning

Current studies show that AI-assisted tools offer significant opportunities for English learning by enabling personalized learning that adapts to learners' needs and skill gaps, shifting away from fixed learning paths (Selvi et al., 2025). They also support the enhancement of dynamic and interactive content, which allows learners to deal with materials actively and improve both engagement and learning outcomes as compared with traditional approaches (Holmes et al., 2019). In addition, AI brings about more formative and collaborative feedback, where both AI systems and teachers provide immediate and targeted support to correct learners' misconceptions (Holmes et al., 2019). Furthermore, AI develops student creativity by exposing learners to a wide range of views and informational diversity, which in turn facilitates knowledge acquisition, absorption, and combination processes (Wang et al., 2026).

Despite its potential opportunities, the integration of AI in ESL learning offers several challenges that need careful consideration. The first concern is the accuracy and reliability of AI

content generated. Though AI can produce language with correct grammar, due to a lack of contextual and cultural understanding, it may lead to superficial or misleading interpretations (Creely, 2024). As a result, learners who rely on AI outputs without critical thinking may develop an incomplete understanding of language use.

The second challenge is overreliance on AI tools among learners, which is viewed as “a significant risk” for learners (Zhai et al., 2024). Where learners overly depend on AI to write, translate, or solve problems, they are less likely to engage in critical thinking and language production activities. This is especially true for non-English major students who may not have strong self-regulation skills (Le & Nguyen, 2022). In short, the overuse of AI can negatively affect the level of critical thinking, turning learners into passive recipients of information rather than being actively involved in the learning process (Dergaa et al., 2023; Kasneci et al., 2023; Tian & Zhang, 2025). This implies that overreliance on AI can prevent learners from analyzing and evaluating the available information independently.

Another major ethical concern arising out of the use of AI includes issues related to data privacy, academic integrity, and responsible AI use. Learners are at a risk of revealing sensitive information about themselves while interacting with AI systems. Also, the ease in creating content makes it easy for learners to plagiarize and misuse the AI generated data (Pikhart et al.,2025).

In conclusion, AI is helpful in ESL learning, but its effectiveness depends on how thoughtfully it is used. Rather than replacing the learner’s work, AI must be viewed as an enabling tool that helps to develop critical thinking and independent learning among students.

2.4 Research Gap

An increasing number of studies have investigated English learning among non-English majors in Vietnam. Their subjects revolve around the learner's motivation, autonomy, and language proficiency. Some previous studies have indicated the connection between learners' autonomy and English skills (Ho, 2018). However, most learners have always relied heavily on teacher instructions while struggling to develop their self-regulation skills (Nguyen & Nguyen, 2020; Le & Nguyen, 2022).

Other prevalent difficulties faced by the learners are demotivation, lack of practice opportunities, and lack of confidence in communication (Nguyen, 2024; Nguyen & Pham, 2025). In recent years, there has emerged new research investigating the impact of using AI on learning English. The studies commonly reveal positive results, which include increased language proficiency, motivation, learner autonomy, and opportunities for autonomous learning (Pham & Pham, 2025; Hoang et al., 2025). Experimental data demonstrate the benefits of applying AI-based technologies, such as Chatbots, including the enhancement of speaking skills and increased confidence (Nguyen, 2024).

However, this area remains underexplored when talking about SE students. Bear in mind that they often have to deal with various technologies in their work, and that their studies are associated with specific English demands. Moreover, they have greater advantages in terms of AI literacy compared with students from other majors. With their technical background, many of them may handle the tools beyond ordinary usage by adapting, integrating, customizing and personalizing English learning applications. Thus, the study aims to fill the gap in the existing body of knowledge by investigating AI applications in SE students' English study.

3. Methodology

3.1. Research Design

The study probes into how AI influences SE students' feelings, attitudes, and behaviors. It tries to understand the main concern about whether AI tends to get them motivated or gets in the way of their motivation and learner autonomy, especially in the context where English is not their major.

Data were gathered using online surveys that aimed at identifying variables, including AI usage frequency among SE students, their attitude towards AI, their level of dependence on AI, as well as their perspectives about how AI influences their motivation levels. Likert scale questions were developed, while multiple-choice questions were converted into binary variables. In addition, there are seven open-ended questions to understand the reason why SE students utilize AI tools, what they view as its learning benefits, and what problems they have to deal with. Also, there are some questions focusing on students' views about what needs to be done. Content analysis was employed to identify recurring themes associated with learner autonomy and SE students' expectations from AI-based learning environments.

a. Participants

The sample consisted of 134 undergraduate Software Engineering majors at Ho Chi Minh City University of Foreign Languages and Information Technology (HUFLIT). All were in their third or fourth year. The group was viewed as highly representative for some reasons:

- Their major is Software Engineering of the Faculty of Information Technology. Most of them were studying specialized subjects of the third and fourth year and were familiar with English technical materials. However, they were also under pressure to satisfy the university's English graduation requirements while keeping up with demanding projects in their program.
- In terms of technology, all participants had already used AI tools before the study, and they used those tools in different subjects. This may make the information collected from the sample relevant and suitable for the research.
- Gender factor is not what the paper refers to, as the SE students are nearly male-dominated, with female students accounting for under 10% of the participants.

b. Instrumentation & Data Collection

Data for this paper were collected through a structured questionnaire consisting of 25 items for an online survey. The instrument was designed to cover five interrelated dimensions.

- **Group 1**: A list of items (Items 1–7) enquires about students' awareness of learning outcomes and the importance of English. This is to assess students' grasp of the university requirements of learning outcomes and the career expectations they have about the labor market.
- **Group 2**: Difficulties and Barriers (Items 8–10), this group of items is designed to address the challenges and pressure students face when they have to work with English materials in technical subjects, especially common difficulties in English for Special Purposes (ESP) courses.

- **Group 3**: Interaction with AI Tools (Items 11–16), examined why students use AI at university, e.g., to obtain code explanations, translate documents, correct grammar, or receive support for English learning, and it also considered their prompt engineering abilities.
- **Group 4:** The group is about the impact on students' motivation and autonomy (Items 17–19), which is to assess changes in learning attitudes and the extent to which students rely on technology.
- **Group 5:** Students' recommendations (Items 20–25): The students collected qualitative input on AI use across language skills, and they also recorded students' views on how teaching practices might need to change for teachers of specialized subjects and teachers of English under evolving learning conditions like changing learning environments, technologies, AI use, or online learning.

The questionnaires were disseminated in April 2026. The survey was designed to help objectivity in responses, and the student participation was voluntary and anonymous.

3.4. Data Standardization and Analysis

Before analysis, responses collected via Google Forms were cleaned and standardized to ensure the dataset conformed to the needs of statistical modelling. Two complementary procedures were applied.

3.4.1. Processing of Quantitative Data:

All quantitative responses were coded before descriptive and correlational analyses were performed. The categorical variables were then transformed into numerical forms for statistical handling. For example, academic year and proficiency level were assigned numerical codes (e.g., YEAR: 1 = third-year students, 2 = fourth-year students). For analysis purposes, responses to multiple-choice questions were converted into binary variables (0 = not selected, 1 = selected) to calculate the frequency and percentage of each category. Finally, indicators of learner behavior were created by combining related responses using average or total scores, depending on the type of items.

3.4.2. Content analysis of open-ended responses (Qualitative)

The analysis was applied to open-ended responses, which was carried out in three steps.

- The first step was to clean the text data by removing duplicate entries and ambiguous responses.
- The second step was thematic coding, where responses were categorized into core themes regarding students' perspectives on AI tools and pedagogical proposals.
- The third step involved keyword extraction from students' responses for improvement suggestions. A frequency-based scan was performed to identify the most common student requests, which served as the basis for the recommendations in Section 5.

4. Results and Discussion

4.1. Results

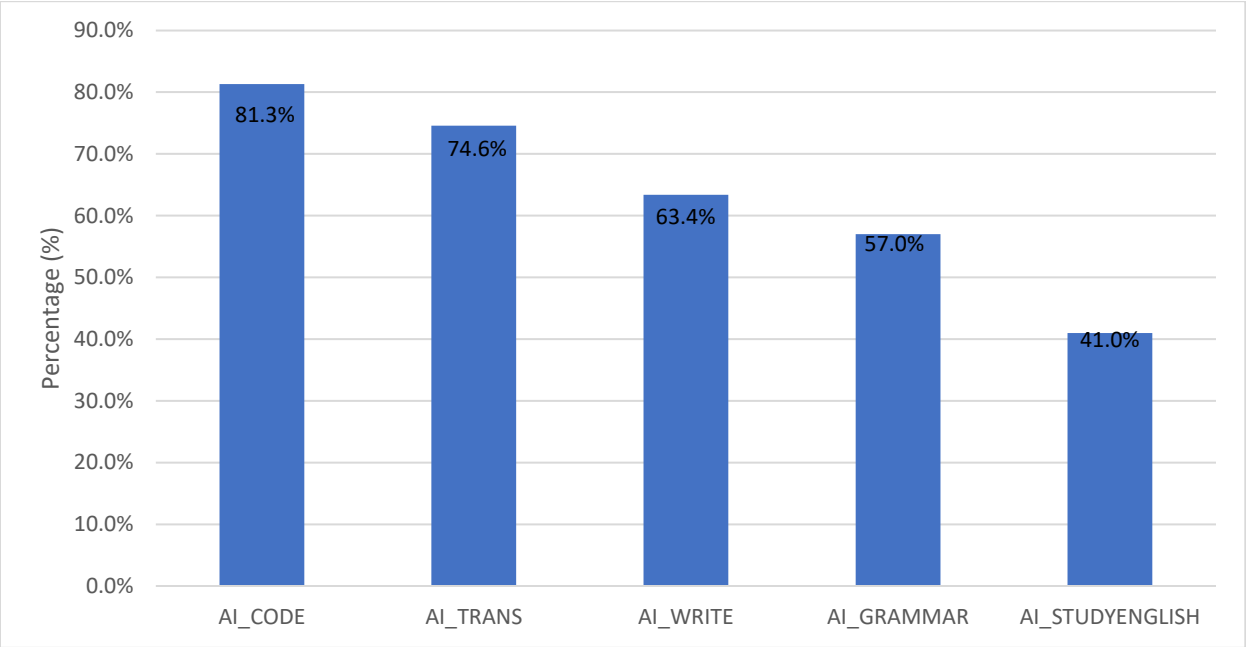
4.1.1. Current Perceptions and Challenges (Score Overview)

As shown in Table 1, SE students report a very strong awareness of English as both a graduation requirement and a resource for future employability. At the same time, the growing presence of AI tools is associated with a noticeable change in how students approach English language-related work.

Table 1

Level of awareness of English learning via AI

Variable (Scale)	Mean	Std. Dev.	Interpretation
IMPORTANCE (1-5)	4.37	0.95	Students show a very high awareness of the importance of English.
SUBJECTIVE (1-5)	3.61	1.12	Students tend to believe that deep understanding of terminology is necessary rather than relying solely on AI.
DIFFICULTY_SCORE (0-6)	2.70	1.79	Moderate level of difficulty in accessing technical English.
READING LEVEL (1-3)	1.67	0.66	Most students feel pressure when reading original materials without translation tools.



Note: N = 134. Higher mean scores in IMPORTANCE and SUBJECTIVE indicate stronger agreement. DIFFICULTY_SCORE represents the cumulative index of perceived barriers, while READING LEVEL reflects the perceived necessity of translation tools during independent reading.

4.1.2 AI Usage Purposes

The patterns of use indicate that AI serves purposes extending well beyond basic translation. Figure 1 reports that the most frequent application is the explanation of code logic and technical terminology (AI_CODE: 81.3%); English-Vietnamese translation to support reading comprehension (AI_TRANS: 74.6%), assistance with technical report writing (AI_WRITE: 63.4%) and grammar review or practice (AI_GRAMMAR: 57%). By contrast, only 41% of respondents indicate that they use AI explicitly to learn English itself (AI_STUDYENGLISH), for instance, through grammar work or active vocabulary development.

Figure 1

The primary purpose of using AI

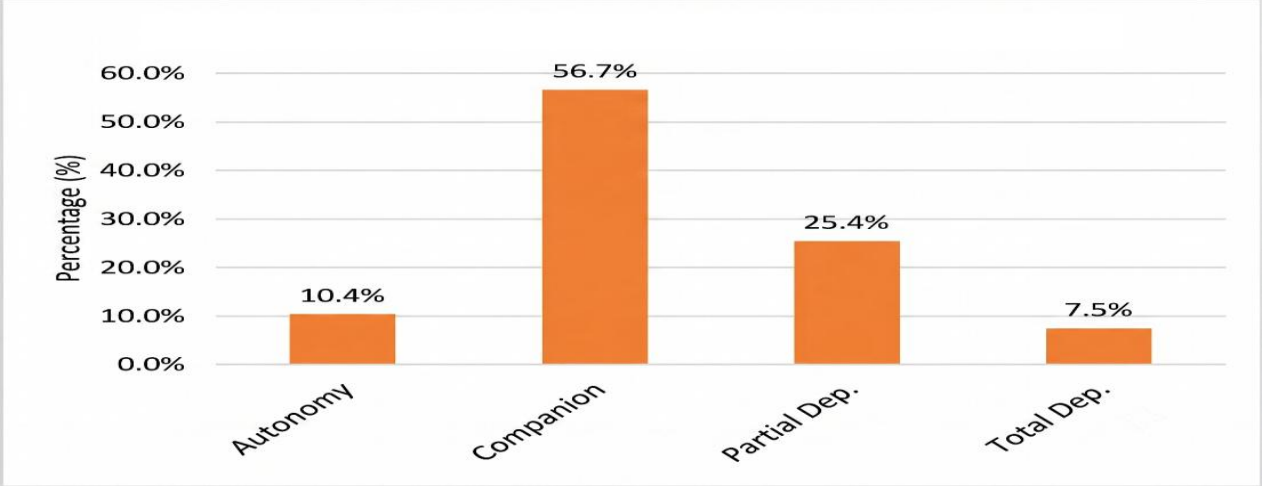
4.1.3. Impact of AI on Learning Motivation (Motivation Change)

Table 2

Learning Motivation and Levels of AI Dependency (N = 134)

Component	Category	n	%	Interpretation
Motivation change	Increased motivation	63	47.0	AI reduces barriers and fosters new learning interests.
	No change	44	32.8	AI is perceived as a normal, supportive tool.
	Decreased motivation	27	20.2	Indicates reduced effort due to reliance on AI.
Dependency level	Full autonomy	14	10.4	AI is used only when necessary.
	Companion	76	56.7	AI supports learning while students retain control.
	Dependence (partial)	34	25.4	Students may struggle without AI support.
	Dependence (total)	10	7.5	
Verification behavior	Always/Frequently	82	61.2	Reflects stronger autonomy and critical thinking.
	Sometimes/Never	52	38.8	Risk of accepting inaccurate AI-generated information.

Note. N = total number of respondents.



From the empirical evidence presented in Table 2, it can be seen that a variety of attitudes exist concerning motivation, as follows**:**

- Increasing motivation (47%): In this group, the motivation levels are high since AI reduces their anxiety about dealing with complex documents.
- No change (32.8%): The participants see AI as a neutral tool, and therefore, it does not influence motivation levels.
- Decreasing motivation (20.2%): This is an alarming group because the students become accustomed to thinking, "AI is doing everything, and thus I don't have any reason to study."

4.1.4. AI Dependency Levels

Figure 2

Level of Dependency on AI in Language Learning

The distinction between "companionship" and "dependency" is particularly noteworthy:

- 56.7% of participants view AI as a companion
- 25.4% acknowledge partial dependency
- 10.4% show a high level of autonomy
- 7.5% report total dependency

Further analysis shows that dependency and motivation are related. Students who view AI as a "companion" have the highest motivation score (2.51), and those who are "totally dependent" have the lowest (1.70). This suggests that AI improves motivation only if learners have control over its application.

4.1.5. Autonomy vs. Dependence

Table 2 shows that the majority of students (56.7%) view AI as a 'companion', but a significant percentage 32.9% say they are partially or fully dependent. More specifically, the dependence on AI can be seen in Table 3, the students had to encounter high pressure when they read English materials without AI assistance.

The mean pressure score of 1.7 suggests a potential risk of overreliance in ESL learning contexts.

Table 3

The Level of Pressure Experienced by SE Students

State of Pressure	Level (3-point Likert scale)	Description	Frequency (n)	Percentage (%)
Students feel a high level of pressure	1	High Pressure when reading English materials without AI assistance	58	43.28%.
Moderate Pressure	2	Students feel a moderate level of pressure when reading English materials without AI assistance.	62	46.27%
Low Pressure	3	Students feel a low level of pressure when reading English materials without AI assistance.	14	10.45%
Mean Pressure Score	**1.7**			
Total			134	100%

Note. *The scale ranges from 1 (High Pressure) to 3 (Low Pressure). A lower mean score indicates higher perceived pressure*

.

4.1.6. Students' evaluation and proposal of an AI application in English learning

Analyzing the content of open-ended responses resulted in the following themes:

- The first thing is that AI is perceived as a tool that makes complicated information easily comprehensible and removes cognitive barriers. The majority of students indicated that the application of AI makes learning easier. One student wrote, “AI does the work quite well”, another that “AI can translate according to the specific context.” Other responses emphasized its speed, convenience, and utility across all aspects of language acquisition, frequently describing AI as a personal *"tutor."*

- Second, many students raised critical thoughts regarding potential overreliance on AI. Specifically, the necessity of cross-checking of AI outcomes was expressed by several learners. One of the students wrote: “AI might not be 100% accurate for expert languages”, another stated that “students should only keep a part and adjust the others”.

- Third, a tendency to learning in the context where AI is more broadly applied became clear among the learners; there was a clear move toward “practical”, “AI-integrated” and “less theory-oriented” learning. Students suggested project-based learning and more practice-oriented instruction, and the provision of explicit training regarding proper AI utilization, focusing on how to maximize efficiency while avoiding overreliance.

- Lastly, they suggest integrating AI into teaching and learning, improving teachers' AI literacy, and guiding students on using AI effectively. They also stress the need to make the curriculum more practical and relevant to students' majors, to promote learner proactivity, and to adopt more competency-based and project-oriented assessment approaches.

Table 4

Students' feedback and Standardized Themes

Standardized Themes	Percentage	Recommendations
THEME_AI_ROLE	23.13%	Integrate AI into teaching and learning
THEME_TEACHING	29.85%	English teachers should be AI-literate; subject lecturers should guide prompt use, promote innovation in teaching practices.
THEME_CURRICULUM	9.70%	Incorporate practical elements and integrate skills into major-related projects.
THEME_STUDENT	10.45%	Students should be proactive and develop a full range of skills
THEME_ASSESSMENT	17.16%	English assessment should be practical, competency-based, and integrated into major projects.
THEME_GENERAL	9,70%	No specific opinion

5. Discussion

5.1. Students' perceptions of AI-assisted English Learning

SE students have a high perception of the importance of learning English, rating its significance at 4.37. These results are consistent with the relevance of English in accessing technical literature and collaborating globally (Chin & Lah, 2025). At the same time, changes in learning practices are currently happening in the direction of introducing AI to learning (Selvi et al., 2025).

According to open-ended survey responses, students regard AI as a tool making the process of learning less stressful and simplifying access to complex information. They often describe it as "fast" and "convenient," even comparing it to "tutors." Therefore, it appears that AI plays an important role in students' interaction with English in the educational process. Verification of AI outputs was mentioned frequently by many students as necessary, especially for specialization, indicating their critical thinking skills (Benson, 2011; Yang, 2026).

Figure 1 shows that students who find AI useful tend to integrate it into various learning activities, including understanding technical concepts, supporting reading comprehension, writing reports, and reviewing grammar. Moreover, students' frequent verification of AI-generated information indicates an awareness of the need for critical evaluation, reflecting certain aspects of learner autonomy. However, the findings also suggest that perceived usefulness do not always lead to independent learning behaviors. While 56.7% of students consider AI a learning companion, a proportion of students still experience partial or complete dependence on AI.

5.2. AI Use: Performance vs. Learning

As shown in Figure 1, AI is mainly used to perform tasks aimed at code explanation, translation for reading, and writing. Thus, the presented results are consistent with its nature as a supplementary aid in the context of educational institutions, which suggests that students prefer performance to long-term language learning (Tian & Zhang, 2025). This is further confirmed by the answers offered by the respondents, focusing on efficiency and getting tasks done rather than developing language skills more deliberately. Although such an approach is appropriate in the case of students in technical fields (Chin & Lah, 2025), it reflects the gap between its potential as a pedagogical technique and its implementation. Previous studies have also found that such an approach to the matter may limit students' opportunities to develop comprehension (Dergaa et al., 2023; Kasneci et al., 2023).

5.3. AI, Motivation, and Learner Engagement

There is evidence of contradictory results concerning motivation among the respondents. While 47% of them report a rise in motivation, 20.2% of them mention reduced motivation. So, it is claimed that the results are partly aligned with the first hypothesis: the more frequent SE students use the AI tools, the higher motivation they may show. This is mainly because AI decreases anxiety, provides instant help, and boosts their confidence to fulfil English-related assignments. However, even though SE students often use the tools, it does not automatically lead to high motivation, as some SE students admitted they had less effort when AI implemented the learning tasks for them.

Within the framework of Self-Determination Theory, AI may serve as a motivational factor by promoting perceived competence and helping to complete the task (Ryan & Deci, 2000). According to the qualitative results, AI helps students to eliminate fear and intimidation associated with learning, thereby making the process motivating. However, some students report the opposite –specifically, that AI makes it possible to reduce efforts because the tools "execute the work quite well." In other words, motivation seems to be affected by the manner of the technology's use rather than the technology itself (Dörnyei, 2001).

Therefore, the results partially support the hypothesis concerning the relationship between regular interactions with AI-assisted learning tools and high motivation. Table 2 suggests that AI can reduce learning barriers, decrease anxiety when dealing with complex English materials, and encourage students to engage more with English learning. Nevertheless, some students experienced decreased motivation due to overreliance on AI, which may reduce their effort to develop their own skills.

5.4. AI Dependency and the Autonomy–Motivation Relationship

The findings raise issues concerning autonomy and dependency when SE students work with AI. According to the participants' responses, although they are aware that AI outputs may contain inaccuracies (they often verify or correct them), many still rely on AI to complete their tasks. Furthermore, the data suggests a relationship between autonomy and learning motivation: high autonomy corresponds to relatively high motivation ($M = 2.51$), while high dependency is associated with low motivation ($M = 1.70$). In other words, these findings are consistent with Benson's (2011) view regarding autonomy as a central role in sustaining motivation and effective learning. That means SE students with higher autonomy demonstrate higher motivation compared with those who rely heavily on AI.

5.5. Challenges and Opportunities

AI clearly helps reduce language barriers and enables better access to technical materials. Students often describe it as fast and convenient, making it easier to understand and complete tasks. However, moderate difficulty levels (M= 2.70) and low confidence in independent reading (M = 1.67) show that students still rely on AI for support. The qualitative responses also point to the risk of putting in less effort, especially if AI is used instead of thinking critically. The students want more hands-on, AI-integrated instruction that focuses less on theory and provides help with prompt writing and effective AI usage. This indicates that the main challenge lies not in accessing AI but in promoting intentional, critical, and self-directed use in language learning environments.

The findings strongly support the second hypothesis concerning the relationship between SE students' attitudes toward AI and their awareness of both advantages and drawbacks. Many students view AI positively because it makes learning faster, more convenient, and less stressful, describing it as a personal "tutor" that helps simplify complex information. At the same time, students demonstrate awareness of AI limitations, particularly concerns about inaccurate information and overdependence. Several respondents emphasized the need to verify AI-generated content and adjust AI responses rather than accept them completely.

6. Conclusion & Recommendations

6.1. Conclusion

In accordance with the findings, SE learners are aware of the usefulness of English language in academics and professional career, yet they do use AI for certain tasks and not more often for learning purposes. In fact, AI mainly helps them in understanding technical content and doing academic work. Thus, it stresses the practical use of English in the SE field.

In addition, the impacts of AI on motivation among the SE students was not the same. Further evidence suggests that whereas AI may reduce anxiety related to learning, it may promote passivity to create 'a passive receiver'- not an active learner. As a result, it is important to emphasize and help SE students be aware of AI paradox in the way it can prove to be helpful as well as harmful. When students use AI effectively, they will find it easier to be more independent and self-motivated, which may have significant benefits for them. Using it excessively and unconsciously, on the contrary, may prevent learners from engaging fully and developing the ability to learn independently.

In conclusion, the successful integration of AI in English learning relies not just on access but also on how it is utilized. These results indicate the need for guided usage of AI, focusing on encouraging critical thinking, independence, and a learning-oriented approach, along with IT efficiency of SE students.

6.2. Recommendation

From the above results, recommendations are made to improve the learning of English by AI-supported tools for SE students, SE lecturers and lecturers of English.

First, AI-supported tools should be used in the learning process of English. AI should be utilized by addressing both students' academic and professional needs; therefore, students should be asked to use it not merely as a tool for performing certain tasks but as a part of the learning process to promote learning the language, thinking process and engagement.

Second, in terms of English courses designed in the curriculum for SE students, they should be revised to ensure a more appropriate alignment between expected English learning outcomes and the practical demands of SE students in their future career. Greater concentration should be placed on students' communicative competence and their use of English in SE context. Furthermore, the IT Department should provide SE students with practical training in prompt engineering to apply AI-assisted tools for learning English more effectively. SE lecturers could encourage students to initiate AI-based projects, guide them in customizing AI tools for English learning, design and personalize learning software to meet their individual learning needs. Moreover, task design in curriculum should be oriented to integrating AI with English learning.

Third, traditional evaluation is not aligned with AI-supported learning. Since AI tools currently are capable of producing simply memorized or template responses readily, assessment must be adapted to examine how students employ AI tools in an informed, appropriate, and effective manner when completing learning tasks.

Fourth, it is crucial to emphasize that AI is a supportive tool, not a replacement for learning. Thus, SE students need to develop the skills for independent and self-guided learning. Also, to prevent overreliance on AI, it is important to encourage students' active participation in the learning process.

Finally, Vietnamese universities should provide a clear policy on how AI can and should be used ethically and effectively. Such a policy should address academic integrity and offer guidelines to help students use AI responsibly.

Acknowledgements

I would like to thank my partner, Nguyen Van Chuong (MA) and my son, Nguyen Do Nguyen (ECE2023, Vietnamese-German University) for their assistance with English language revising and editing my manuscript.

I would also like to thank 134 software engineering (SE) students at HUFLIT University for participating in the survey for this research.

Last but not least, some AI-based tools including Grammarly and Chat GPT have also helped me a lot with checking grammar, spelling errors, and sentence structures.

#83 UNPACKING THE BARRIERS: KEY DETERMINANTS OF PUBLIC SPEAKING ANXIETY AMONG ENGLISH MAJOR UNDERGRADUATES AT HUFLIT

Vo Quoc Viet[1]

Abstract

The impact of public speaking anxiety (PSA) was found to significantly affect the quality of presentation among undergraduates majoring in English. This study aims to investigate environmental, psychological, linguistic, and experiential barriers contributing to PSA among English majors at Ho Chi Minh University of Foreign Languages and Information Technology (HUFLIT). This study utilized a convergent parallel mixed-methods, cross-sectional design. Quantitative data collection was carried out via Likert-scale surveys among 133 participants. Results were further established via in-depth semi-structured interviews with 15 highly anxious participants. Results revealed that environmental factors, particularly time pressure and unfamiliar topics (mean=3.85), are the most important statistical stressors. Moreover, the experience of large audiences further heightened anxiety among participants. From a psychological point of view, English majors face an "English major burden" which demands flawless performance (mean=3.79). Such a situation triggers considerable evaluation apprehension. From a linguistic point of view, grammar and vocabulary-related issues evoke considerable anxiety among the participants. Moreover, insufficient practice and rote memorization create an experiential avoidance pattern. The results suggest that these barriers are interconnected. Linguistic hindrances heighten psychological fears, which are further heightened by environmental triggers to create an experiential avoidance pattern. To alleviate PSA among English majors at HUFLIT, it is recommended that participants be desensitized to environmental triggers and encouraged to focus more on effective communication rather than grammar and vocabulary. Additionally, participants should be encouraged to engage in low-stakes practice to overcome rote memorization.

Keywords: public-speaking, anxiety, barriers, mixed-methods

1. Introduction

English major students' target language is not only the tool to communicate with the world, but it is also their main professional orientation. Unfortunately, when students need to present their knowledge in a public performance, the language abilities that once boosted their spirits seem to trigger their fears. Public speaking anxiety (PSA) transforms academic presentations into huge obstacles, especially when the academic and professional identities of those whose job relies heavily on their English proficiency turn into barriers. Therefore, PSA becomes an important challenge that obstructs undergraduates from obtaining academic success and a rewarding career.

1.1. Research Context

For HUFLIT students whose majors are English, PSA appears to be an increasing problem in teaching that needs urgent and thorough examination. As far as observed, a remarkable percentage of English major undergraduates enrolled in public speaking courses in the second semester of 2025 - 2026 have shown medium to high PSA levels. This initial assessment was later confirmed by quantitative data collected with the Personal Report of Public Speaking Anxiety (PRPSA), developed by McCroskey (1970). That specific affective barrier acts as a significant block for students in giving an oral performance in public contexts.

1.2. Research Question

This study concentrates on addressing the following research question: What are the primary environmental, psychological, linguistic, and experiential barriers contributing to public speaking anxiety among English major undergraduates at HUFLIT?

1.3. Purpose of the Study

The present study aims to investigate the contributing factors to PSA in English major undergraduates at HUFLIT. In order to achieve this goal, scientific research will focus on identifying these barriers and proposing evidence for pedagogical approaches aimed at minimizing students' anxiety in public speaking and improving oral presentation confidence.

1.4. Structure of the Paper

The rest of this research paper is organized into five key sections. Firstly, the literature review provides an overview of the previous literature regarding PSA and emphasizes such barriers as psychological, linguistic, environmental, and experiential ones. Secondly, the methodology section includes details about the methods, participants, and procedures used to gather and analyze data related to public speaking anxiety (PSA) among undergraduates at HUFLIT. Thirdly, the empirical data obtained are presented in the Results part, where the crucial factors that determine the emergence of anxiety in the sample are disclosed. Their analysis and interpretation are carried out in the Discussion part, where the obtained results are discussed in the light of existing literature. Finally, the Conclusion and Recommendations part provides the main conclusions and recommendations for English teachers, HUFLIT administration, and all higher education institutions in Vietnam on how to help their students cope with PSA.

2. Literature Review

Public speaking anxiety (PSA) remains a significant challenge to communicative competence and academic success in higher education, especially for the second and foreign language learners. For English majors, public speaking ability is not just an outcome or a requirement but a part of their personal and professional identity, which is why PSA can severely affect both oral production and psychological well-being. For the comprehensive exploration of the complex phenomenon of PSA, this literature review will critically assess recent research across four conceptual dimensions: environmental, psychological, linguistic, and experiential barriers.

2.1. Primary Determinants of Public Speaking Anxiety

2.1.1. Environmental Barriers

The learning environment plays a significant role in intensifying PSA among students. One of the main sources of such anxiety is evaluation anxiety, where students fear negative

evaluation from the instructor and classmates. The presence of external pressure, such as the threat of overt criticism in the classroom, creates a frightening atmosphere for presenters, and instructional and classroom management techniques have a direct impact on the level of stress experienced by the students (Valdivieso Quinaluisa, 2024; Monib, 2025). Strict feedback from the teacher and a lack of emotional and academic support increase student stress. Consequently, when students are expected to perform or respond orally without the foundation of a psychologically safe, communicative environment, they inevitably experience debilitating performance pressure.

2.1.2. Psychological Barriers

Extensive research demonstrates that students' PSA are affected by internal psychological processes. In particular, Le (2024) and Qayyum et al. (2024) found that intrinsic features, especially a student's overall confidence in learning a second or foreign language, contribute significantly to the level of speaking anxiety. Such anxiety is often expressed as strong psychological barriers. For example, Boonchuayrod (2025) revealed that students had high cognitive anxiety in answering spontaneous questions during public speaking. Moreover, Qayyum et al. (2024) pointed out that the fear of making mistakes and the lack of confidence to speak frequently result in students' silence and hinder their oral production. From a motivational perspective, Alamer and Almulhim (2021) pointed out that being competent and socially connected aided in reducing particular kinds of anxieties. In contrast, controlled motivation heightened overall language anxiety.

2.1.3. Linguistic Barriers

Language anxiety is associated with language learners' assumed communicative competence; a student who assumes their competence in the target language is low is more anxious than those who assume high competence in a communicative situation. According to Qayyum et al. (2024), these language constraints are identified as the major hindrances in communication. Moreover, English-speaking ability is identified as a vital aspect influencing PSA at all stages of performance (Viwattanabunchong, 2017).

From the micro-linguistic point of view, specific deficiencies in vocabulary and grammar hinder performance in speaking (Monib, 2025; Qayyum et al., 2024). Monib (2025) found that excessive concern for perfect grammar while speaking spontaneously interferes with communication. Besides the restrictions imposed by syntax, phonological precision is equally important; according to Karmida et al. (2024), mispronunciation reduces the student's level of oral competence and hence affects their confidence. Therefore, as illustrated by Le (2024), a lack of knowledge or confidence in one's linguistic ability causes emotional distress because insufficient vocabulary and inaccurate pronunciation create intense anxiety in academic presentations.

2.1.4. Experiential Barriers

The intensity of PSA varies depending on the specific stage of the assignment, the academic level of a student, and institutional curriculum design. Viwattanabunchong (2017) described PSA in four separate stages of task performance: pre-preparation, preparation, pre-performance, and performance. Whereas research shows that anxiety persists through all four stages, it peaks at the performance stage. However, the intensity of anxiety that arises at this final stage depends heavily on the field of study of the student and their educational level. To be specific, English majors report significantly lower performance anxiety than non-majors, owing to a curriculum designed in such a way that there is regular oral production practice and continuous formative instructions (Boonchuayrod, 2025). Additionally, the degree of education

is an important factor when determining the intensity of PSA. Undergraduates and students in master's programs have twice as much anxiety as doctoral students (Lintner & Belovecov, 2024).

2.2. Research Gap

Despite a large number of previous studies focusing on PSA in a global context (e.g., Thailand, South Korea, Brunei, Saudi Arabia, Indonesia, Ecuador, the Czech Republic, the Philippines, and Pakistan), there is still a gap in the existing literature. Specifically, there has been a lack of empirical research investigating the combined effects of environmental, psychological, linguistic and experiential barriers on PSA of English major undergraduates in Vietnam higher education context.

2.3. Rationale for Conducting the Research at HUFLIT

An investigation into the PSA of English major undergraduates at HUFLIT is justified by the following institutional and instructional considerations:

2.3.1. Pedagogical Optimization and Curricular Refinement

Frequent oral practice often serves as an effective remedy to alleviate PSA, yet the emphasis on stringent evaluation and competition might create a paradoxical pedagogical situation wherein practice, by increasing stress levels, could exacerbate PSA rather than alleviate it. The rationale behind this issue is: If practice causes a considerable amount of anxiety in the classroom, the educational interventions currently in use may be less effective in achieving the desired impact on performance outcomes. Research findings have indicated that the alleviation of PSA needs instructional methods that can create a comfortable, student-centered environment, and consequently, identifying the particular aspects of environmental, psychological, and linguistic and experience based that lead to the emergence of PSA among HUFLIT English major undergraduates will permit us to propose and to implement appropriate pedagogical interventions for mitigating such negative affect. In addition, the research outcomes will provide empirical evidence for effective evaluation and modification of the present speaking curricula.

2.3.2. Alignment with Academic Standards and Professional Expectations

HUFLIT is a higher education institution specializing in training students in foreign languages and international communication. Its mission involves the development of highly proficient linguistic graduates to prepare them for direct entry into the global labor market. This challenging goal has resulted in a competitive, high-stakes learning environment that can potentially induce significant distress among undergraduates. In such an environment, PSA is viewed as a substantial hindrance to the successful academic performance and later employability of the graduates. Hence, considering the training objectives of the institution for future international communicators, PSA represents a challenge for its fulfillment and also a pedagogical impediment for effective teaching.

3. Methodology

This section will describe the methods of study that were applied to reveal the factors contributing to PSA amongst the English major undergraduates of HUFLIT. It gives comprehensive information about the research design, participants, sampling strategy, tools used to gather data and methods of analyzing data.

3.1. Research Design

A mixed-method cross-sectional design was adopted in this research. The combination of different methodologies allowed not only to broaden but also to deepen the obtained data. In particular, a convergent parallel design was applied, whereby quantitative and qualitative data were collected at the same time, analyzed separately and then merged at the interpretation stage.

3.2. Population and Sample

The targeted population for this study included undergraduate students majoring in English at HUFLIT who either currently took or had finished attending the public speaking class. The following dual-sampling design was employed to select participants for the research:
3.2.1. Quantitative Component:

A convenience sampling technique was used to recruit 133 undergraduate students who would take part in completing the main survey.

3.2.2. Qualitative Component:

A purposeful sampling technique was used to choose a particular subset of 15 highly-anxious students out of all participants recruited for conducting qualitative semi-structured interviews.

3.3. Data Collection Instruments

Data collection involved two tools that were developed to satisfy mixed-method research requirements:

3.3.1. Online Survey:

The questionnaire, based on a Likert scale consisting of 5-point items, aimed at gathering data about the broadness of information belonging to the obstacles contributing to PSA: environmental, psychological, linguistic, and experiential barriers.

3.3.2. Semi-structured Interviews:

In order to find appropriate participants for the second component of the study, the Personal Report of Public Speaking Anxiety (PRPSA) was conducted among all selected participants. Subsequently, fifteen students with the highest scores on the PRPSA test were interviewed. The interviews used open-ended questions that would enable participants to reflect upon their experiences and identify internal barriers.

3.4. Data Collection Procedure

All the processes involved in the data collection were carried out systematically over six weeks in January and February 2026 as follows:

3.4.1. Ethics and Consent:

Ethical approval was granted, and informed consent was digitally gathered from all 133 participants before collecting the required data. Participants' rights, privacy, and the objective of the study were clearly informed.

3.4.2.Survey Distribution:

The survey on determinants of PSA and PRPSA was conducted simultaneously using Google Forms.

3.4.3. Interview Execution:

After 15 participants with the highest scores in PRPSA had been recognized, they were interviewed utilizing the semi-structured interview format. Each of these interviews took about 20 to 30 minutes to complete. All interviews were recorded after obtaining verbal consent from each participant.

3.5. Data Analysis

Both quantitative and qualitative data analyses were carried out separately before being triangulated and merged into one analysis.

3.5.1. Quantitative Analysis:

Descriptive analysis was performed on the data obtained through the Likert scale survey to measure the average scores of survey items and standard deviation values.

3.5.2. Qualitative Analysis:

The interview transcripts were analyzed using thematic analysis established by Braun and Clarke (2006). This involved the coding process for generating themes related to identifying environmental, psychological, linguistic, and experiential barriers contributing to PSA based on participants' personal perceptions and experience.

3.5.3. Integration:

As a result of adopting the convergent parallel design in this study, the descriptive statistics results and themes from the qualitative data were compared in order to identify the convergence or divergence between the two data sources related to the research question.

3.6. Expected Outcomes and Limitations

The first and foremost expected outcome is the identification of environmental, psychological, linguistic, and experiential barriers that contribute to PSA among HUFLIT English major undergraduates and provide insights for pedagogical interventions. Nonetheless, certain limitations must be admitted in regard to this research methodology. First, the use of surveys and interviews may lead to methodological limitations in the research, because of respondent self-reporting bias, in which participants may over- or under-report their degree of anxiety, based on social norms or personal subjective memory. Second, the generalizability of the findings to English majors at other universities is potentially limited, due to the nature of the sample drawn from one site (HUFLIT).

4. Results

A convergent parallel mixed-methods design was utilized to integrate the quantitative and qualitative datasets. This triangulation facilitates a comprehensive, holistic understanding of the primary determinants contributing to PSA among English major undergraduates at HUFLIT.

4.1 Environmental Barriers

As illustrated in Table 4.1, environmental factors emerged as the most significant barrier, yielding the highest overall mean score among all the analyzed categories (overall mean=3.75). The factors with the greatest impact on students' performance include the apprehension toward unfamiliar topics alongside time pressure (mean=3.85), closely followed by presentations in front of a large audience (mean=3.80). Correspondingly, interviewees noted that public speaking in front of a big crowd deepens the feeling of isolation and vulnerability, while heightening a sense that the audience is uninterested. Moreover, strict time pressure intensifies students' anxiety levels.

Table 4.1

Environmental Determinants Contributing to PSA

Items	N	Mean	Std Deviation	Min	Max
Large audiences increase my speaking anxiety.	133	3.796992	1.172665	1	5
Strict lecturer evaluation heightens my nervousness.	133	3.676692	1.11157	1	5
Peer pressure or comparison with classmates affects me.	133	3.669173	1.112748	1	5
Unfamiliar topics or time limits make me anxious.	133	3.849624	1.048059	1	5
Overall mean:		3.74812			

4.2. Psychological Barriers:

Table 4.2 demonstrates that psychological barriers are the second most impactful obstacle in causing PSA (overall mean=3.67). Primarily, this result is driven by intense perfectionist tendencies within the students' major field of study (mean=3.79), a concern highlighted during their discussion of the "Burden of the English Major Identity", where students felt a heavy institutional and professional pressure to use language perfectly.

Table 4.2

Psychological Determinants Contributing to PSA

Items	N	Mean	Std Deviation	Min	Max
I worry about others judging or criticizing my speech.	133	3.736842	1.05812	1	5
I lack confidence in my ability to deliver a good speech.	133	3.654135	1.08044	1	5
I fear forgetting my content or making mistakes in front of an audience.	133	3.781955	1.032343	1	5
I avoid voluntary speaking activities due to fear.	133	3.406015	1.206282	1	5
I feel pressure to perform perfectly due to being an English major.	133	3.789474	0.992797	1	5
Overall mean:		3.673684			

4.3. Linguistic Barriers:

As indicated in the quantitative data in Table 4.3, linguistic barriers were found to be a major problem for students. The mean score for the overall category is 3.64, which indicates a high level of anxiety in their competence in the target language. The greatest obstacle in the category for PSA was limited vocabulary, with a mean score of 3.80, closely followed by concerns about accurate grammar, with a mean score of 3.68. Supporting the quantitative results, qualitative interviews revealed how the fear of grammatical errors and the possibility of being misunderstood put non-native English major presenters in a state of cognitive self-monitoring. The constant evaluation of the grammatical structure of each utterance overloads their cognitive capacity, so that they have to prioritize the correctness of the syntax over the natural flow of communication.

Table 4.3

Linguistic Determinants Contributing to PSA

Items	N	Mean	Std Deviation	Min	Max
My limited vocabulary causes anxiety during speeches	133	3.796992	1.099307	1	5
I struggle with pronunciation/fluency in English presentations.	133	3.413534	1.194227	1	5
Grammar errors make me nervous when speaking publicly.	133	3.684211	1.032564	1	5
I feel my English skills are not sufficient for academic presentations.	133	3.676692	1.171304	1	5
Overall mean:		3.642857			

4.4. Experiential Barriers:

Experiential barriers had one of the lowest overall mean scores in the quantitative sections (mean = 3.45), and the range of responses is shown in Table 4.4. The highest mean in the category is lack of practice (mean=3.75). Even though previous negative experiences scored lower (mean = 3.25). While past negative experiences had a lower average score of 3.25, qualitative findings indicate that these experiences still deeply affect undergraduate students' PSA. These experiences can create a negative internal dialogue that leads students to self-handicap and to actively work against their academic success. Besides this negative internal dialogue, participants noted that avoidance of speaking opportunities, often due to past negative experiences, leads directly to a lack of practice. Thus, students don't get the systematic desensitization that's necessary to lower their anxiety, and they also miss out on opportunities to reframe their prior negative experiences more positively. Another way students try to overcome their fear of forgetting their content is through rote memorization. This coping strategy is ineffective because the fixed, linear nature of memorized text means that forgetting a single transitional word can cause the organization of the entire presentation to collapse.

Table 4.4

Experiential Determinants Contributing to PSA

Items	N	Mean	Std Deviation	Min	Max
Lack of practice opportunities contributes to my anxiety.	133	3.75188	1.03284	1	5
Negative past feedback from lecturers/peers affects my speaking confidence.	133	3.24812	1.227254	1	5
Previous bad experiences (e.g., embarrassment) linger.	133	3.315789	1.1894	1	5
Insufficient feedback/training worsens my anxiety.	133	3.466165	1.062793	1	5
Overall mean:		3.445489			

5. Discussion

The primary objective of this research was to investigate the environmental, psychological, linguistic, and experiential barriers contributing to PSA among English major

undergraduates at HUFLIT. The integration of the quantitative and qualitative analyses reveals that these four types of barriers are not separate but interconnected to form a loop of anxiety. The environmental factors have the strongest impact on students' PSA, followed by psychological and linguistic barriers, while experiential factors show the lowest anxiety levels, but cause long-term avoidance of public speaking practice.

5.1. Environmental Barriers: Unfamiliar Topics, Time Pressure, and Audience Scale

Among various determinants, environmental barriers recorded the highest mean score for PSA among HUFLIT English major undergraduates (overall mean = 3.75), with particular contributions from unfamiliar topics, strict time pressure (mean = 3.85) and audience scale (mean = 3.80). These results partially align with the studies of Valdivieso Quinaluisa (2024) and Monib (2025), who noted that external pressure, such as being ridiculed or criticized by other people, creates an unfriendly and threatening environment for students to perform ineffectively. However, this research extends beyond these foundational works because it shifts the main concentration of environmental anxiety. Although previous literature tends to focus on the effects of the environmental pressure of comparing oneself to peers and being judged by teachers, HUFLIT undergraduates found that the situational limitations of the testing environment, such as a large audience and strict time pressure, created a strong feeling of isolation. This implies that the situation - performing in front of many people under strict time pressure - has a more noticeable influence on the occurrence of PSA than peer comparisons.

5.2. Psychological Barriers: "The Burden of the English Major Identity"

Psychological barriers emerged as the second-most influential factor contributing to PSA (overall mean = 3.67). This is consistent with earlier studies conducted by Le (2024) and Qayyum et al. (2024) that point out low self-confidence levels and cognitive fears as the main causes for speech anxiety. The results obtained from this study reinforce their theory, particularly regarding the fear of forgetting content or making mistakes (mean = 3.78). Crucially, our results add a new perspective to this psychological aspect in terms of "The Burden of the English Major Identity" (mean = 3.79). Unlike general language learners, HUFLIT English majors face intense, internalized pressure for perfectionism rooted in their chosen specialization. The result from this study directly contradicts the theory of Alamer & Almulhim (2021), which proposes that competence and relatedness mitigate specific forms of anxiety. For the students in the study, public speaking is closely connected to their academic and professional identity, transforming normal presentations into high-stakes evaluations. This intense pressure leads to cognitive anxiety and fear of evaluation.

5.3. Linguistic Barriers: The Cognitive Self-Monitoring State

Linguistic barriers are major contributors to students' PSA, with an overall mean of 3.64. The main concerns were vocabulary limitations (mean = 3.80) and the fear of grammatical inaccuracy (mean = 3.68). The findings of this study support the theories advanced by Qayyum et al. (2024) and Viwattanabunchong (2017) that language competence is essential in developing speaking confidence. Moreover, the qualitative integration provides a profound insight into the psychological aspect of the theory about grammar discussed by Monib (2025), who states that overemphasizing grammar impedes fluency. Empirical evidence of this issue can be found in the current study in the form of the cognitive self-monitoring state. Under the fear of being misunderstood or negatively evaluated, presenters become locked in an ongoing process of real-time editing to ensure syntactic accuracy. Consequently, this intense cognitive

load and psychological strain result in anxiety actions like hand shaking and trembling of the voice.

5.4. Experiential Barriers: The Avoidance of Public Speaking Practice and Rote Memorization

Experiential barriers got the lowest overall quantitative average score (mean=3.45). This finding supports Boonchuayrod's (2025) argument that English majors have less performance anxiety than non-majors due to an immersive curriculum that includes a lot of presentations. However, qualitative data deeply undermine the assumption that low frequency or low quantitative scores imply a low psychological impact. For instance, although a lack of practice opportunities scored relatively high within this category (mean = 3.75), negative past feedback scored the lowest numerically (mean = 3.25), yet it serves as a powerful psychological trigger. Rather than fading over time, these negative past experiences form destructive internal dialogues that result in "self-handicapping," which ultimately drives students to avoid practice. By avoiding voluntary speaking opportunities, students prevent themselves from gaining the practice needed to reframe those negative memories into positive experiences. Students tend to rely on rote memorization to avoid the anxiety of repeating past failures. In theory, this coping strategy is precarious; the loss of one connecting word can bring down the entire edifice of a presentation, ultimately resulting in a poor performance.

5.5. The Loop of Public Speaking Anxiety

This paper provides comprehensive insights into PSA, demonstrating how four types of determinants are interrelated. First, language insecurity is the starting point of this process, where the need to be grammatically perfect, syntactically controlled, and to use a limited vocabulary creates a strong fear of being evaluated negatively. This fear of negative evaluation psychologically is intensified by the environmental factors, such as large audience size, high institutional expectations and time pressure. All these determinants together lead to a high level of performance stress, which makes students adopt ineffective coping strategies such as avoiding public speaking practice and using rote memorization. These strategies do not bring relief or improve linguistic competence, but they actually make the original language anxiety worse, and keep the loop going.

6. Conclusion

Employing a convergent parallel design to examine the key determinants of PSA of HUFLIT English major undergraduate students, the results of this study confirm that PSA is caused by a network of interconnected environmental, psychological, linguistic, and experiential obstacles. Specifically, environmental barriers were found to be the most severe constraint (overall mean=3.75), mainly due to limited time to present unfamiliar topics, and the feeling of isolation when speaking in front of a large crowd. Closely following this, psychological barriers ranked second (overall mean=3.67), because of students' burden of being an English major, who had to speak without making mistakes, in addition to the fear of being evaluated. Similarly, linguistic barriers (overall mean=3.64) rooted in insufficient vocabulary and grammar fear, which led to an intense state of self-monitoring in which students over-edit their sentences during performance, thus losing focus on effective communication. On the other hand, experiential barriers had the lowest mean score (overall mean=3.45). Past negative learning experiences and feedback, along with the psychological and linguistic demands for perfect delivery in front of an audience, form an invisible barrier that compels students away from practicing public speaking, which leads to insufficient preparation, thus greatly triggering PSA.

Recommendations

Based on the findings of this study, the following pedagogical and institutional recommendations are proposed to mitigate PSA among students.

For Educators

- *Scaffold Presentation Difficulty:* Students should be allowed to choose familiar topics for their initial major presentations. This scaffolding will enable students to build confidence and develop time management skills before engaging with more complex subject matters.
- *Foster collaborative Interaction:* To mitigate the sense of isolation experienced by the presenter, interactive components such as structured question and answer sessions should be incorporated in lesson planning. This design shifts frightening one-way presentations into collaborative conversations.
- *Reorient Evaluation Rubrics:* Communicative competence and presentation efficacy should be prioritized over grammatical accuracy in assessment criteria. By allowing students to speak without disciplinary measures for minor mistakes, the real-time grammar self-correction process will be broken. This will allow for a more natural delivery.
- *Discourage Rote Memorization:* Instructors should avoid requiring students to deliver perfect content that is based on memorization during their presentations. Instead, build confidence in their speaking and give them practical tools to present well through a short outline using improvised practice.

For the University:

- *Establish Low-Anxiety Practice Environment:* Universities should create non-threatening conditions for students to practice public speaking without being graded, through review sessions, English speaking clubs, or debating contests, where students can accumulate positive experience in making presentations and alleviate anxiety
- *Build Positive Communicator Identity:* Provide institutional orientation or counseling programs so that the burden of linguistic perfection expected from non-native English major students can be eliminated. Students should realize that making errors is inevitable in language learning.

#84 ESL INTEGRATION IN JAPANESE READING INSTRUCTION: EXPLORING THE ROLE OF ENGLISH IN SUPPORTING JAPANESE READING COMPREHENSION AMONG SENIOR JAPANESE-MAJOR STUDENTS AT VNU-HCM UNIVERSITY OF SOCIAL SCIENCES AND HUMANITIES

Vu Doan Lien Khe[1]

Abstract

As Vietnam transitions toward an ESL environment, many students face "language attrition" where their English proficiency declines while focusing on a third language (L3) like Japanese. This case study explores a practical pedagogical approach implemented in Japanese reading classes for fourth-year students at the University of Social Sciences and Humanities (USSH). To tackle this issue, the author introduced a bilingual dynamic that replaces traditional Japanese-Vietnamese translation with Japanese-English "live translation" and vocabulary mapping.

This method encourages students to bridge two foreign languages, gradually creating a cognitive link that may strengthen both. By mapping complex Japanese structures to English counterparts, students deepen their understanding of Japanese nuances while keeping their English active and functional for professional use. To evaluate the model, a mixed-methods research design was employed, involving surveys and qualitative feedback from senior Japanese majors. To make classroom observations more systematic, students' "live translation" performance was observed in class with a focus on semantic accuracy, lexical equivalence, and response latency.

Findings suggest that ESL integration can enhance Japanese textual analysis and is associated with higher reported confidence and cross-linguistic flexibility for many students. Such results are vital for graduates entering a competitive labor market where "English+1" is a highly sought-after asset. This study offers a practical framework for educators to create English-rich environments within diverse curricula, aligning with the HUFLIT INTESOL 2026 goals of fostering English as a versatile tool for student employability in Vietnam's evolving education landscape.

Keywords: ESL integration, Japanese reading, L3 acquisition, English attrition, HCMUSSH, multilingualism.

1. Introduction

In the current educational landscape of Vietnam, the transition toward an ESL (English as a Second Language) environment has placed unique demands on multilingual learners. At the Department of Japanese Studies, Faculty of Oriental Studies, University of Social Sciences and Humanities, VNU-HCM, senior students often face a subtle but persistent challenge:

[1] *Ph. D., University of Social Sciences and Humanities, Vietnam National University Ho Chi Minh City, Faculty of Oriental Studies* vukhejp@hcmussh.edu.vn

“language attrition”. While they are heavily focused on mastering Japanese (L3) for their future careers, their English (L2) skills, which they spent years building, tend to stagnate or “fade away” due to a lack of practical use in the specialized curriculum.

For years, the standard approach to teaching Japanese reading has been a direct bridge between Japanese and Vietnamese. While this helps with basic comprehension, it unintentionally creates a linguistic wall that keeps English out of the picture. In today’s job market, where "English + 1" is often the minimum requirement, letting English proficiency slip away during the final years of university represents a missed opportunity for graduates.

The pedagogical approach investigated in this study emerged from the author’s classroom observations while teaching fourth-year Japanese reading courses. Many students demonstrated strong Japanese reading skills yet struggled to maintain confidence in English communication. To address this issue, the author introduced a bilingual instructional model in which students were encouraged to use English as a cognitive bridge when interpreting Japanese vocabulary, grammar, and textual meanings. Rather than relying exclusively on Japanese-Vietnamese translation, students were invited to explore Japanese-English equivalences and participate in spontaneous “live translation” activities. The intention was not to replace Vietnamese but to create additional opportunities for students to activate English in a meaningful academic context.

Despite growing interest in multilingual education, translanguaging, and cross-linguistic transfer, relatively little research has examined the integration of English into Japanese reading instruction within Vietnamese higher education. Previous studies have primarily focused on bilingual education or the acquisition of individual foreign languages, while the pedagogical potential of English as a supporting language for Japanese reading comprehension remains underexplored. Consequently, empirical evidence regarding students’ perceptions, benefits, and challenges associated with this instructional approach is still limited.

Building upon theories of language attrition, cross-linguistic transfer, and multilingual education, this study aims to examine whether the integration of English into Japanese reading instruction can serve as an effective instructional approach for maintaining students’ English proficiency while supporting Japanese language development. More specifically, the study investigates students’ awareness of English attrition, their perceptions of the bilingual instructional model, the influence of English proficiency on those perceptions, and the advantages and challenges associated with using English as a mediating language in Japanese reading classes. In doing so, the study contributes empirical evidence to ongoing discussions surrounding multilingual pedagogical practices in Vietnamese higher education.

Research Objectives

Based on the aforementioned research gap, this study aims to examine the effectiveness of integrating English into Japanese reading instruction as a pedagogical strategy for supporting multilingual language development. More specifically, this study pursues the following objectives: (1) to investigate students’ awareness of English attrition, (2) explore their perceptions of the bilingual instructional model, (3) examine whether these perceptions vary according to English proficiency levels, and (4) identify the benefits and challenges associated with the use of English as a mediating language in Japanese reading classes.

Research Hypotheses

Guided by the theoretical perspectives of language attrition, cross-linguistic transfer, translanguaging, and cognitive load, the study proposes the following hypotheses:

H1: Students will generally demonstrate positive perceptions toward the integration of English into Japanese reading instruction.

H2: Students with higher levels of English proficiency will report more positive perceptions of the bilingual instructional model than students with lower levels of proficiency.

H3: The integration of English into Japanese reading instruction can contribute to maintaining students' engagement with English while facilitating Japanese reading comprehension.

2. Theoretical framework and methodology

2.1 Theoretical framework

2.1.1. Language attrition in the multilingual learning contexts

This study begins with the concept of *Language Attrition*, which is the gradual fading of a learner's previously acquired English (L2) as their attention shifts toward mastering Japanese (L3) (Kopke & Schmid, 2004). In a multilingual setting, language systems continuously interact and compete for mental effort rather than functioning independently (Herdina & Jessner, 2002). This research aims to reactivate learners' underused English by giving it a meaningful role within the Japanese learning environment. Consequently, when learners devote substantial attention to acquiring a new language, previously learned languages may become less accessible over time.

This phenomenon is particularly relevant in the Vietnamese higher education context, where students majoring in Japanese often devote most of their academic efforts to developing Japanese proficiency while using English less frequently. Recent studies suggest that language attrition is not merely a matter of forgetting vocabulary or grammar but also involves reduced confidence, decreased fluency, and diminished willingness to use the language actively (Schmid & Kopke, 2017; 2019). Therefore, maintaining meaningful opportunities for English use throughout university education has become an important pedagogical concern.

Within this context, the present study considers ESL integration as a potential strategy for mitigating language attrition by providing students with opportunities to reactivate English while engaging in Japanese reading activities.

2.1.2. The Interdependence Hypothesis and Cross-linguistic transfer

Rather than viewing languages as rivals, this study draws on Cummins' *Interdependence Hypothesis*, which proposes that linguistic abilities can be shared and reactivated through a *Common Underlying Proficiency* (Cummins, 2000). According to this framework, different languages share a *Common Underlying Proficiency (CUP)*, through which linguistic knowledge, cognitive skills, and literacy abilities may transfer across languages.

This perspective is closely associated with the concept of cross-linguistic transfer, which refers to the influence of one language on the learning and processing of another. Research has demonstrated that multilingual learners frequently draw upon previously acquired linguistic knowledge when interpreting new language forms and meanings (Cummins, 2021). Such transfer may occur at lexical, semantic, syntactic, and metacognitive levels.

By encouraging students to connect Kanji meanings with their English equivalents, the model applies *Translation in Language Teaching (TILT)* not as rote practice, but as a bridge that strengthens both languages in tandem.

In the present study, English is conceptualized as a mediating language that can facilitate Japanese reading comprehension. By encouraging learners to identify connections between Japanese expressions and English equivalents, the instructional model seeks to activate prior linguistic knowledge and strengthen multilingual awareness. Rather than viewing English and Japanese as competing systems, this approach treats them as complementary resources that may mutually reinforce learning.

In the Vietnamese context, the transition towards an ESL environment as part of the National Foreign Languages Project has redefined how students approach multilingualism. Researchers emphasize that for Vietnamese learners, the interaction between multiple foreign languages requires a strategic pedagogical shift to optimize cognitive resources (Nguyen & Nguyen, 2019).

2.1.3. Translanguaging as a multilingual pedagogical practice

Recent developments in multilingual education have challenged traditional assumptions that languages should be kept strictly separate in classroom instruction. Translanguaging theory argues that multilingual learners possess an integrated linguistic repertoire from which they flexibly draw according to communicative needs (Garcia & Wei, 2014; Wei, 2017).

The classroom model examined in this study aligns with translanguaging principles by encouraging students to utilize English when interpreting Japanese vocabulary, grammar, and textual meanings. Such practices enable learners to mobilize their full linguistic resources while developing greater awareness of relationships among languages. Furthermore, translanguaging has been identified as an effective approach for supporting multilingual skills in increasingly globalized educational environments (Cenoz & Gorter, 2022).

2.1.4. Cognitive load theory and the language threshold

Despite the potential benefits of multilingual pedagogies, the simultaneous activation of multiple languages may also increase cognitive demands. *Cognitive Load Theory* proposes that learning effectiveness depends on the limited capacity of working memory to process information (Paas & Ayres, 2014). When instructional tasks require learners to manage several linguistic systems simultaneously, excessive cognitive load may hinder comprehension and learning outcomes.

Related to this concern, the *Language Threshold Hypothesis* suggests that learners require a minimum level of proficiency before they can effectively benefit from cross-linguistic transfer (Cummins, 2017). Students with stronger English proficiency may be better equipped to utilize English as a cognitive support tool when reading Japanese texts, whereas learners with weaker English backgrounds may experience confusion, mental fatigue, or reduced confidence.

Consequently, the effectiveness of ESL integration is likely to vary according to learners' existing language competence. This perspective provides an important framework for interpreting differences in students' perceptions and experiences within the bilingual instructional model investigated in the present study.

2.1.5. Conceptual framework of the study

Drawing upon *Language Attrition Theory*, the *Interdependence Hypothesis*, *Translanguaging Theory*, and *Cognitive Load Theory*, the present study conceptualizes ESL integration as a pedagogical mechanism through which English can function as a cognitive

bridge in Japanese reading instruction. The framework assumes that meaningful use of English may help reduce language attrition and facilitate cross-linguistic transfer; however, the effectiveness of such an approach may be moderated by learners' existing English proficiency and cognitive capacity. These theoretical perspectives collectively inform the investigation of students' perceptions, experiences, and responses to ESL-integrated Japanese reading activities.

2.2 Methodology

This study employed a mixed-methods case study design to capture the implementation of ESL integration in Japanese reading instruction. A mixed-methods approach was selected because it enables the researcher to combine quantitative evidence with qualitative insights, thereby providing a more comprehensive understanding of students' perceptions and experiences regarding the bilingual instructional model.

This research was carried out at the Department of Japanese Studies, Faculty of Oriental Studies, USSH, VNU- HCM. The participants consisted of 51 fourth-year students enrolled in a Japanese Reading Comprehension course during the 2025-2026 academic year. These students were selected because they had accumulated substantial learning experience in both English and Japanese and were therefore in a suitable position to reflect on issues related to language attrition, multilingual learning, and cross-linguistic interaction. Furthermore, as students approaching graduation, they represented a population for whom maintaining both English and Japanese proficiency is particularly relevant to future employability.

The scope of this study was deliberately limited to students' perceptions, attitudes, and experiences regarding the integration of English into Japanese reading activities. The research did not attempt to measure actual improvements in English or Japanese proficiency through standardized language tests. Instead, the study focused on how learners perceived the effectiveness, practicality, benefits, and challenges of the instructional approach. Consequently, the findings should be interpreted within the specific context of Japanese-major students at a single institution and may not be generalized to other educational settings.

Data were collected through a structured survey comprising two complementary parts. The quantitative section used 5-point Likert scale items to measure student satisfaction, vocabulary retention, and perceived cognitive effort. The qualitative section invited open-ended reflections, giving space for students to share their challenges and feelings of mental fatigue. Together, these data sources provided both statistical rigor and a more personal view of the classroom atmosphere. Prior to data collection, the questionnaire was reviewed by two specialists in language education to ensure content validity and alignment with the research objectives. Minor revisions were made based on their feedback to improve clarity and relevance.

In addition to the questionnaire, classroom observations during "live translation" sessions were used to note students' use of English as a mediating language. The observations focused on semantic accuracy, lexical equivalence and response time, there by providing qualitative support for interpreting the survey results.

The internal consistency of the questionnaire was examined using Cronbach's alpha. The overall reliability coefficient for the nine Likert-scale items was $\alpha=.789$, indicating acceptable internal consistency according to commonly accepted standards for educational research (Taber, 2017). Furthermore, the subscale measuring perceptions of ESL integration demonstrated satisfactory reliability ($\alpha=.758$). These results suggest that the instrument was

sufficiently reliable for investigating students' perceptions of English attrition and ESL integration in Japanese reading instruction.

Table 1. Reliability analysis of the questionnaire

Scale	Number of items	Cronbach's Alpha
English attrition	2	.506
ESL integration effectiveness	5	.758
Career relevance	2	.638
Overall questionnaire	9	.789

As shown in **Table 1**, the overall questionnaire achieved an acceptable level of internal consistency (α = .789). The ESL Integration Effectiveness subscale demonstrated the highest reliability (α = .758), while the lower coefficients observed in the two-item subscales may be attributed to the limited number of items rather than substantial measurement problems.

Quantitative data were analyzed using SPSS 26.0. Descriptive statistics (Mean and Standard Deviation) established a baseline for student perceptions, followed by a one-way ANOVA comparing three proficiency groups, Pre-intermediate, Intermediate, and Advanced, to examine whether perceived "cognitive overload" differed significantly among them. Given that the classroom model relies on English as a mediating language, it was considered essential that participants possess at least a pre-intermediate level of L2 competence. Students with very limited English proficiency were not targeted in this case study, as they might be more vulnerable to cognitive overload rather than benefiting from scaffolding effects. Finally, thematic coding was applied to the qualitative responses, allowing the numerical findings to be interpreted through the authentic voices and experiences of the participants.

Qualitative responses were analyzed using thematic analysis following the framework proposed by Braun and Clarke (2006). The analysis involved familiarization with the data, generation of initial codes, identification of recurring themes, review and refinement of themes, and interpretation of findings. Coding was conducted iteratively to enhance consistency, and the resulting themes were continuously compared with the original responses to ensure interpretive validity. The qualitative findings were subsequently used to complement and explain patterns identified in the quantitative analysis.

2.3 Research delimitations and limitations

Several delimitations should be acknowledged. *First*, the study focused exclusively on fourth-year Japanese-major students at the USSH, VNU-HCM. *Second*, the investigation centered on students' perceptions and experiences rather than objective measures of language proficiency. *Third*, the bilingual instructional model was implemented within a Japanese Reading Comprehension course and may not reflect learning conditions in other language courses or institutions.

In addition, the relatively small sample size and the use of self-reported data may limit the generalizability of the findings. Future research could incorporate larger participant groups, longitudinal designs, and direct assessments of language performance to provide a more comprehensive evaluation of ESL integration in multilingual learning environments.

3. Discussion and findings

3.1. A multimodal and bilingual approach in the classroom

The intervention implemented in this research was designed as a student-centered, multimodal environment that prioritizes genuine understanding over rote translation. In this model, the classroom is divided into small groups, each responsible for presenting a specific reading passage. The presentation phase follows a "non-Vietnamese" guideline for explanation, but participation in English use remains voluntary. When defining new vocabulary or complex Kanji, the presenting group is encouraged to avoid the mother tongue and to experiment with Japanese definitions, Japanese synonyms, visual aids, realia, gestures, and, where possible, English equivalents to convey meaning. The ultimate aim is not to force English into the classroom, but to help students realize that once Vietnamese is set aside, they can flexibly draw on multiple resources (especially their long-acquired L2 English, to interpret and explain the L3). This force-free, multimodal strategy encourages students to engage with Japanese through various cognitive channels, reducing the immediate reliance on Vietnamese.

Following the vocabulary presentation, the rest of the class participates in a "live translation" challenge. This phase is designed to be low-pressure yet intellectually stimulating. Students are invited to translate the reading content into Vietnamese or, as a preferred challenge, into English without the aid of dictionaries. This spontaneous translation process is intended to test their immediate linguistic reflexes. During this time, both the presenting group and the teacher act as facilitators, monitoring the "live" outputs to provide immediate feedback on accuracy and nuance.

The final stage of this model involves a collaborative confirmation of the text's meaning. After the students have attempted their translations, the teacher provides the "standard" or polished version prepared by the students in advance. This ensures that while the process is creative and bilingual, the final learning outcome remains academically precise. By treating English not as a mandatory requirement but as an optional tool for those who wish to experiment, this paper argues that the classroom can become a more dynamic space, where Japanese texts are interprted through a broader, more international perspective, not only through Vietnamese.

3.2. Results and findings

3.2.1. Participant profile and engagement rate

This research was conducted within the fourth-year cohort at the Department of Japanese Studies (USSH, VNU-HCM), where the typical class size ranges from 25 to 32 students across three groups. Out of a total population of approximately 85 students, this paper successfully gathered 51 valid responses, achieving a 60% participation rate. This level of engagement provides a reliable snapshot of the student body's diverse linguistic backgrounds.

The findings revealed a significant "proficiency gap" among the participants. While a majority (72.5%) possess a solid N2 level in Japanese, their English proficiency (L2) is far less uniform. Approximately 45% of respondents are at or below the Pre-intermediate level (IELTS 5.0 equivalent), while only 14% have reached the Upper-intermediate or Advanced stages. This diversity is essential for this paper's analysis, as it highlights that the effectiveness of the classroom intervention is not one-size-fits-all but varies according to individual linguistic capital (Hulstijn, 2015). This proficiency imbalance is particularly relevant to the theoretical assumptions underlying the study. From the perspective of language attrition, the findings suggest that English proficiency may become increasingly vulnerable when learners devote substantial attention to Japanese language development. At the same time, the diversity of English proficiency levels provides an appropriate context for examining whether students'

responses to ESL integration vary according to their existing linguistic resources. The distribution of English proficiency levels is illustrated in **Figure 1**.

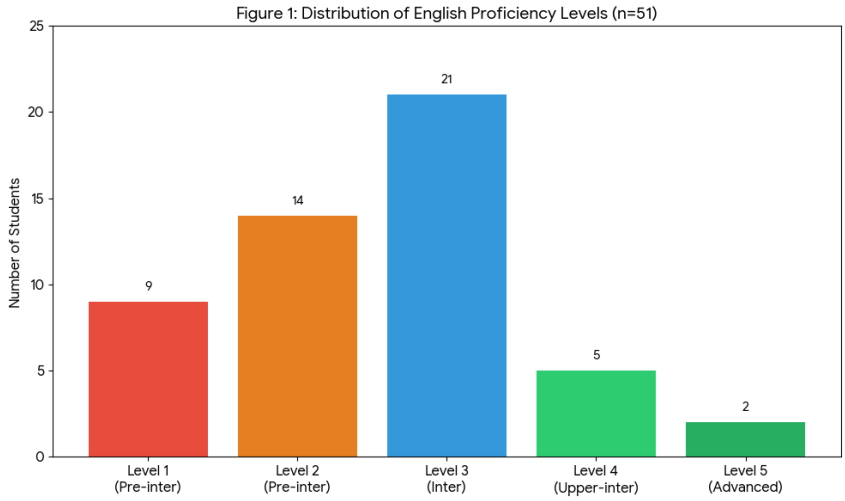

Figure 1. Distribution of English proficiency levels among the surveyed students (n=51)

Source: Compiled by the researcher from survey data.

3.2.2. Quantitative findings

The descriptive statistics indicate a generally high level of awareness regarding English attrition among the participants. The mean score for perceived decline in English proficiency (M=4.18, SD=1.05) reveals that many students recognized a reduction in opportunities to actively use English while concentrating on Japanese language studies. Similarly, the relatively high score for difficulty in switching between Japanese and English (M=4.26, SD=0.89) reflects the linguistic challenges associated with managing multiple foreign languages simultaneously.

Participants also reported generally positive perceptions of the bilingual instructional model. Scores related to vocabulary retention through English equivalents (M = 3.90, SD = 0.98), perceived enjoyment (M=3.63, SD=0.87), and excitement in identifying cross-linguistic connections (M=3.76, SD=0.93) suggest that students viewed ESL integration as a potentially valuable learning strategy. These findings point to a cross-linguistic transfer mechanism consistent with Cummins' *Interdependence Hypothesis*, in which prior linguistic knowledge is reused across languages.

Moreover, the highest mean scores were observed in items related to career readiness and employability. Participants strongly agreed that multilingual competence represented an important professional asset, as reflected in the high ratings for confidence in applying to multinational companies (M=4.37, SD=0.72) and the perceived importance of the "English + 1" model (M = 4.36, SD=1.04). These findings suggest that students viewed ESL integration not only as a learning strategy but also as a means of enhancing their future professional competitiveness. Descriptive statistics for the key variables are summarized in **Table 2**.

Table 2: Descriptive statistics of student perception (n=51)

Survey items (Key variables)	**Mean (M)**	**Std. Deviation (SD)**
A. Language attrition awareness		

1. Perception of English skills "fading"	4.18	1.05
2. Difficulty in switching between JPN and ENG	4.26	0.89
B. Bilingual model effectiveness		
3. Vocabulary retention via equivalents	3.90	0.98
4. Interesting challenge (instead of pressure)	3.63	0.87
5. Excitement in finding linguistic connections	3.76	0.93
C. **Practicality & career**		
6. Confidence in applying to MNCs	4.37	0.72
7. Necessity of "English + 1" model	4.36	1.04

Source: Calculated from the primary survey data (2026) by the author

A one-way ANOVA was conducted to examine whether students' perceptions differed according to English proficiency level. The analysis revealed a statistically significant difference in perceived interest across proficiency groups ($p < .05$). Students with higher levels of English proficiency reported more positive attitudes toward the instructional model, whereas learners in the lowest proficiency group expressed comparatively lower levels of interest and engagement.

This finding supports the *Language Threshold Hypothesis*, which suggests that learners must possess a minimum level of linguistic competence before they can effectively benefit from cross-linguistic transfer. For students with stronger English proficiency, the bilingual instructional model appeared to function as a cognitively stimulating learning strategy that facilitated connections between Japanese and English. In contrast, learners with more limited English proficiency may have experienced difficulties managing the simultaneous activation of two foreign languages.

The findings also align with *Cognitive Load Theory*. While multilingual interaction can promote deeper processing and transfer of knowledge, excessive cognitive demands may hinder learning when students lack sufficient linguistic resources. Consequently, the effectiveness of ESL integration appears to depend not only on the instructional design itself but also on learners' existing proficiency levels. Differences in perceived interest across proficiency levels are illustrated in **Figure 2**.

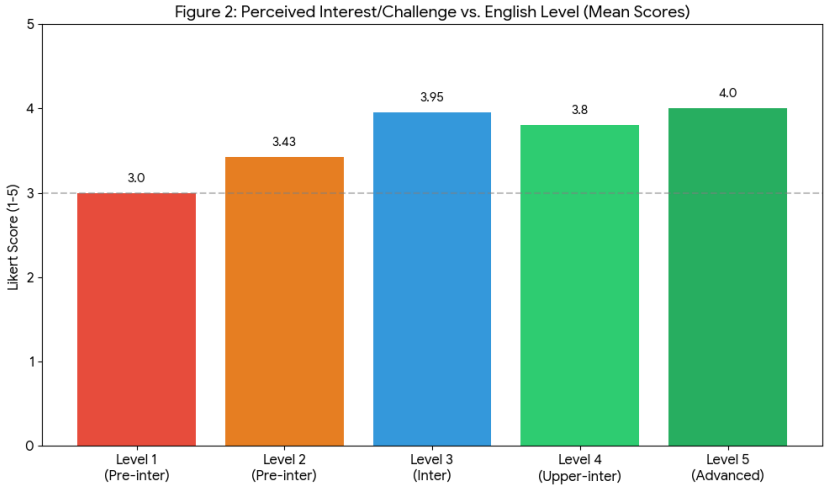

Figure 2. *Mean scores of Perceived Interest versus English proficiency levels*

Source: Extracted from SPSS analysis of survey responses 2026

3.2.3. Qualitative findings

The qualitative responses provided valuable insights into how students experienced the integration of English into Japanese reading instruction. Through thematic analysis, three major themes emerged, which were English as a cognitive bridge, enhanced multilingual awareness, and cognitive burden associated with linguistic limitations. This thematic analysis revealed three recurring themes in students' responses: English as a cognitive bridge, enhanced multilingual awareness and learning motivation, and cognitive burden associated with linguistic limitations.

Theme 1: English as a cognitive bridge for Japanese reading comprehension

A recurring theme across participants' responses was the perception of English as a useful intermediary for understanding Japanese vocabulary and grammatical structures. Many students reported that identifying English equivalents enabled them to process unfamiliar Japanese expressions more efficiently and establish meaningful connections between previously acquired knowledge and new linguistic input.

This finding supports Cummins' *Interdependence Hypothesis*, which proposes that knowledge acquired in one language can facilitate learning in another through shared learning capacity. Rather than functioning as separate linguistic systems, English and Japanese appeared to interact dynamically within students' learning processes. For many participants, English served as a practical scaffold that supported comprehension and promoted deeper engagement with Japanese texts.

Theme 2: Development of multilingual awareness and learning motivation

A second theme concerned the development of multilingual awareness. Participants frequently described feelings of satisfaction when recognizing similarities among languages and successfully drawing connections between Japanese and English. Several students reported that the instructional approach encouraged them to think more critically about language structures and vocabulary relationships rather than relying exclusively on memorization.

These experiences are consistent with recent perspectives on translanguaging and multilingual education, which emphasize the pedagogical value of drawing upon learners' full

linguistic repertoires (Garcia & Wei, 2014; Cenoz & Gorter, 2022). The findings suggest that ESL integration may promote a more flexible and reflective approach to language learning by encouraging students to utilize multiple linguistic resources simultaneously. Furthermore, the ability to engage with more than one foreign language appeared to strengthen students' confidence in their future academic and professional development.

Theme 3: Cognitive burden and linguistic insecurity

Despite the generally positive responses, a third theme highlighted challenges associated with the bilingual instructional model. Participants with lower levels of English proficiency frequently reported feelings of confusion, mental fatigue, and anxiety when attempting to process Japanese through English. For these students, the additional requirement to activate English sometimes increased the complexity of the learning task rather than facilitating comprehension.

This finding can be interpreted through the lens of *Cognitive Load Theory* (Paas & Ayres, 2014), which suggests that excessive demands on working memory may negatively affect learning performance. The results also provide support for the *Language Threshold Hypothesis* (Cummins, 2017), indicating that learners may require a certain level of English proficiency before they can fully benefit from cross-linguistic transfer. Therefore, the benefits of ESL integration may vary across learners, particularly according to their English proficiency levels.

Overall, the qualitative findings complement the quantitative results by revealing both the opportunities and challenges associated with ESL integration in Japanese reading instruction. While many students perceived English as valuable cognitive resources that enhanced multilingual awareness and reading comprehension, others experienced difficulties resulting from limited English proficiency. These findings suggest that the implementation of bilingual instructional practices should remain flexible and responsive to learners' varying linguistic backgrounds. In this sense, the model appears more suitable for students who already possess a relatively stable English foundation, which may help reactivate and sustain their L2 while supporting Japanese reading comprehension.

4. Conclusions and pedagogical implications

The present study investigated the integration of English as a supporting language in Japanese reading instruction among fourth-year Japanese-major students at the USSH, VNU-HCM. Drawing upon theories of language attrition, cross-linguistic transfer, translanguaging, and cognitive load, the study explored students' perceptions of a bilingual instructional model designed to maintain English engagement while supporting Japanese reading comprehension.

The findings indicate that participants generally perceived the integration of English positively. Many students reported that English functioned as a useful cognitive bridge, enabling them to establish meaningful connections between previously acquired linguistic knowledge and new Japanese vocabulary and structures. The results further suggest that ESL integration may contribute to reducing the effects of language attrition by creating opportunities for students to continue using English within their academic learning environment.

At the same time, this study revealed important differences among learners. Students with stronger English proficiency demonstrated greater enthusiasm and adaptability toward the bilingual instructional approach, whereas those with more limited English backgrounds were more likely to experience confusion, frustration, and increased cognitive burden. These

findings support both the *Language Threshold Hypothesis* and *Cognitive Load Theory*, suggesting that the effectiveness of multilingual instructional practices is influenced by learners' existing linguistic resources.

Overall, in this study, students reported that integrating English into Japanese reading instruction may provide a practical way to support multilingual language development among Japanese major students. Rather than treating English and Japanese as competing languages, the study supports the view that they can function as complementary resources that mutually reinforce language learning when implemented appropriately.

Several pedagogical implications can be drawn from the findings of this study. *First*, ESL integration should be implemented gradually and adapted to students' English proficiency levels. While higher-proficiency learners may benefit from more extensive English-mediated activities, lower-proficiency students may require additional scaffolding to prevent excessive cognitive load. *Second*, instructors should adopt translanguaging practices that encourage flexible movement between Japanese, English, and Vietnamese rather than enforcing rigid language separation. Such practices may help learners utilize their full linguistic repertoire and facilitate deeper comprehension of reading materials. *Third*, vocabulary instruction can be enhanced through the systematic incorporation of English-Japanese lexical mapping activities. Encouraging students to identify semantic relationships among languages may strengthen vocabulary retention and promote cross-linguistic awareness. *Fourth*, multilingual reading tasks should emphasize meaning-making rather than direct translation. Activities such as collaborative discussion, vocabulary comparison, and contextual interpretation may help students engage more actively with texts while maintaining meaningful use of English. *Finally*, universities may consider incorporating multilingual instructional approaches into language programs as a means of supporting graduates' employability. In an increasingly globalized labor market, maintaining proficiency in both English and Japanese may provide students with a significant professional advantage.

Several limitations should be acknowledged. *First*, this study was conducted with a relatively small sample drawn from a single institution, which may limit the generalizability of the findings. *Second*, this investigation relied primarily on self-reported perceptions rather than objective measures of language proficiency. *Third*, this intervention was implemented within a specific Japanese reading course and over a limited period of time.

Future studies may expand the sample size, include participants from multiple institutions, and employ longitudinal research designs to examine the long-term effects of ESL integration on both English maintenance and Japanese language development. Furthermore, future research could incorporate standardized language assessments to provide more objective evidence regarding the effectiveness of multilingual instructional approaches.

Form the teacher's point of view, the bilingual model also made classroom interaction more lively, as students had more options for expressing partial understanding before switching back to Japanese.

#85 FACTORS ASSOCIATED WITH THE SCIENTIFIC RESEARCH COMPETENCE OF HUFLIT ENGLISH LANGUAGE STUDENTS IN PROJECT 1 AND PROJECT 2

Quoc Bao Mai[1]

Abstract

This study examines factors associated with the self-assessed scientific research competence (SRC) of English Language students at Ho Chi Minh City University of Foreign Languages - Information Technology (HUFLIT) through Project 1 and Project 2. The study uses a convergent mixed-methods design, combining a quantitative survey of 500 students who had completed both courses with semi-structured interviews with 19 students. Quantitative data were processed with SPSS 26.0 and SmartPLS 4.0 using PLS-SEM, while qualitative data were analyzed thematically. The results show that the measurement model achieved satisfactory reliability, convergent validity, and discriminant validity (HTMT < 0.85). The structural model explained 52.7% of the variance in self-assessed SRC, 37.5% of the variance in overall course effectiveness (OE), and 46.0% of the variance in satisfaction (SAT). Of the 12 hypotheses, 11 were supported. Learning engagement (PE) was the strongest predictor of SRC ($\beta = 0.279$, $p < .001$), followed by assessment and feedback standardization (AS), course design quality and continuity (AL_CW), lecturer/system support (IS), and AI guidance linked with academic integrity (AI). Methodological and academic language barriers (MLB) showed a positive but statistically non-significant relationship with SRC ($\beta = 0.010$, $t = 0.342$, $p = .733$), contrary to the hypothesized negative direction. The interview data suggest that this result may reflect students' awareness of research difficulties and their use of coping strategies (such as AI or peer reliance), rather than only the actual obstructive level of those difficulties. Students still reported difficulties with literature review, SPSS-based data analysis, discussion writing, teamwork, and responsible AI use. The findings provide evidence for improving course design, standardizing rubrics, strengthening formative feedback, and developing clearer guidelines for AI use in academic work.

Keywords: self-assessed scientific research competence, English Language students, research methodology courses, PLS-SEM, assessment and feedback standardization, AI guidance, academic integrity

1. Introduction

1.1. Rationale

In the context of modern higher education, scientific research competence is not only an academic requirement but also an essential skill that helps students develop critical thinking, problem-solving ability, and lifelong learning (Ciraso-Cali et al., 2022; Prosekov et al., 2020). For English Language students, doing scientific research has a more specific and complex nature. They face a "double burden": they must understand research methodology and also

[1] *Corresponding author, Undergraduate Student, Department of English Language, Faculty of Foreign Languages, Ho Chi Minh City University of Foreign Languages - Information Technology (HUFLIT), Ho Chi Minh City, Vietnam, Email: 23DH710401@st.huflit.edu.vn; ORCID: 0009-0002-3382-0809*

overcome barriers in academic language, data analysis, and culture (Ciraso-Cali et al., 2022; Le et al., 2023).

Recognizing this importance, Ho Chi Minh City University of Foreign Languages - Information Technology (HUFLIT) has included two core courses in the English Language program: Project 1 (Data Collection Skills) and Project 2 (Introduction to Scientific Research Methodology). The design of this course sequence shows the university's effort to move from content transmission to outcome-based education, creating constructive alignment in teaching (Biggs, 1996), together with a project-based learning model.

However, in practice, the implementation of research courses still has many challenges. Students often have difficulty identifying research problems, designing instruments, and especially meeting the strict standards of academic English. Moreover, the continuity between the two courses, teaching quality, supporting learning materials, and consistency in assessment through clear criteria are factors that directly are related to the success of developing students' research competence (Brookhart, 2018; Dawson, 2015; Reddy & Andrade, 2009).

Previous studies on students' research competence have mainly focused on describing competence or motivation to participate in research. They have not fully explained the combined roles of course design, lecturer support, assessment rubrics, AI/academic integrity guidance, and language/methodological barriers in the context of two connected Project courses. To address this gap, the topic "Factors Associated with the Scientific Research Competence of HUFLIT English Language Students in Project 1 and Project 2" was conducted.

1.2. Research Objectives

This study aims to identify and analyze the factors associated with the scientific research competence of English Language students at HUFLIT through Project 1 and Project 2. Specifically, the study examines the relationships of learning engagement, lecturer and system support, assessment and feedback standardization, AI use and academic integrity guidance, methodological/language barriers, and course design quality and continuity on students' SRC. Based on quantitative and qualitative findings, the study proposes implications for course improvement and directions for building an SRC framework suitable for English Language students.

1.3. Research Questions

To achieve these objectives, the study focuses on answering three questions:

- What factors are associated with the self-assessed scientific research competence of HUFLIT English Language students in Project 1 and Project 2?
- What is the strength of the relationships between learning engagement, lecturer/system support, assessment and feedback standardization, AI guidance, methodological/language barriers, course design quality, and students' SRC?
- How is students' SRC associated with overall course effectiveness and student satisfaction?

1.4. 1.4. Significance of the Study

Theoretical significance:

This study enriches the academic literature on the scientific research competence of university students, especially in the context of English as a Foreign Language (EFL). The use of a multi-dimensional assessment model (survey and interview) provides a strong mixed-methods approach through triangulation in educational research (Creswell & Creswell, 2009).

Practical significance:

- For students: The study helps students clearly identify difficulties in doing research, including both methodology and academic English, so that they can develop more effective self-regulated learning strategies (Panadero & Broadbent, 2018).
- For lecturers and the Faculty of Foreign Languages (HUFLIT): The study provides empirical evidence for reviewing and adjusting syllabi, standardizing assessment criteria (Brookhart & Chen, 2014; Dawson, 2015), and strengthening the continuity between Project 1 and Project 2.
- For administrators and curriculum developers: The study provides empirical evidence for the university to review and improve the training program, especially the continuity between Project 1 and Project 2, supporting learning materials, assessment rubrics, feedback mechanisms, and guidance on AI use in academic work. On this basis, the program can be adjusted to better match the learning outcomes of the English Language major and the need to develop students' scientific research competence.

2. Literature Review

2.1. Root Theories

To explain the development of SRC and the factors associated with it, this study is based on the following main theories:

2.1.1. Theory of Planned Behavior (TPB)

The Theory of Planned Behavior, proposed by Ajzen (1991), is one of the classic theories used to predict individual intention and behavior. According to TPB, students' research behavior and SRC are affected by three factors: (1) attitude toward the behavior, (2) subjective norms, such as encouragement and support from lecturers and the university, and (3) perceived behavioral control, or students' confidence in overcoming barriers. This theory supports the argument that institutional scaffolding and language/methodological barriers are directly related to students' ability to conduct research.

2.1.2. Constructive Alignment and Outcome-Based Education (OBE)

Constructive Alignment, developed by Biggs (1996), is an important guide for higher education curriculum design. Biggs argues that learning is most effective when there is close alignment among learning objectives or outcomes, teaching methods, and assessment methods. For Project 1 and Project 2, this theory explains why students' SRC may depend strongly on the continuity of course design and the transparency of assessment criteria, or rubrics.

2.1.3. Self-Regulated Learning (SRL)

According to Panadero and Broadbent (2018), self-regulated learning is the process in which learners guide, monitor, and adjust their behavior and thinking to achieve academic goals. In project-based learning environments such as Project 1 and Project 2, active learning engagement and self-assessment are internal drivers that help students turn passive knowledge into real research competence.

2.2. Empirical Literature

2.2.1. Scientific Research Competence and the "Double Burden" in an EFL Context

SRC is a multi-dimensional system that includes the ability to identify problems, design methods, collect data, analyze data, and present findings (Ciraso-Cali et al., 2022). Compared with students in natural science fields, English Language students face a "double burden". First,

they face methodological barriers when learning data analysis concepts (Ciraso-Cali et al., 2022; Davidson & Palermo, 2015). Second, they face academic language barriers. The gap between everyday communication and academic language creates major difficulties in reading academic sources and writing standard reports (Le et al., 2023).

2.2.2. The Role of Assessment for Learning (AfL), Feedback, and Rubrics

Assessment for Learning (AfL) shifts the focus from merely grading students to using assessment as a tool to enhance their learning process (Black & Wiliam, 1998). In complex tasks like scientific research, effective formative feedback provides students with the necessary scaffolding to identify their weaknesses and improve their work iteratively (Hattie & Timperley, 2007). Furthermore, the use of clear and well-designed rubrics is essential in higher education. Rubrics not only standardize assessment criteria among different lecturers but also help students understand academic expectations, thereby developing their evaluative judgement and self-regulation skills (Brookhart, 2018; Dawson, 2015; Reddy & Andrade, 2009).

2.2.3. Artificial Intelligence (AI) and Academic Integrity in Research

The growth of digital tools, open science, and AI is reshaping research practice. Requirements for transparency, open data, and research integrity are becoming more important (Le et al., 2025). Appropriate AI use can support students in data processing and academic writing. However, without clear guidance on academic integrity, AI may replace learners' critical thinking. Therefore, integrating AI guidance into the Project courses is an urgent need.

2.3. Hypothesis Development

Drawing on the theoretical and empirical review above, this study constructs a structural model centering on SRC as the outcome variable. It is predicted by six input factors and then linked to overall course effectiveness and student satisfaction. The 12 hypotheses below are organized in two groups.

Group 1: Factors Affecting Scientific Research Competence (SRC)

Self-Regulated Learning theory treats active learner agency as the primary catalyst for competence development (Panadero & Broadbent, 2018). Healey et al. (2014) further argue that scientific research is inherently participatory: students cannot acquire research skills through passive reception of lecture content alone; rather, they must engage with materials, interact with lecturers and peers, and monitor their own progress over time. Such engagement transforms declarative knowledge about research methods into procedural competence. In the context of Project 1 and Project 2, where students are expected to produce extended research outputs, high levels of engagement - including autonomous resource-seeking, deadline management, and iterative revision - should be associated with a stronger command of the research process.

H1 (+): Active learning engagement (PE) is positively associated with students' SRC.

Vygotsky's concept of the zone of proximal development implies that novice researchers benefit most when guided by knowledgeable others who provide timely scaffolding (Ciraso-Cali et al., 2022; Le et al., 2023). In the HUFLIT context, this scaffolding takes two distinct forms: institutional resources (e.g., Moodle repositories, research templates, handbooks) and supervisory guidance (e.g., formative feedback on draft chapters, consultations on methodology). When either form is insufficient or delayed, students may lose direction at

critical stages such as instrument design or data interpretation, ultimately undermining SRC development.

H2 (+): System and lecturer support (IS) is positively associated with SRC.

The literature on assessment for learning establishes that well-designed rubrics serve a dual pedagogical function: they communicate academic expectations transparently and they provide a diagnostic lens through which students can evaluate - and subsequently improve - their own work (Black & Wiliam, 1998; Brookhart, 2018; Dawson, 2015; Hattie & Timperley, 2007). When rubric criteria are applied consistently across lecturers, students develop evaluative judgement - the capacity to discern quality and to close the gap between current and target performance. By contrast, ambiguous or inconsistent grading erodes trust in the assessment process and can discourage sustained effort.

H3 (+): Assessment and feedback standardization (AS) is positively associated with SRC.

The emergence of generative AI tools (e.g., ChatGPT, Gemini) has introduced a new dimension to research pedagogy. While AI can accelerate literature synthesis, grammar correction, and data exploration, it simultaneously raises concerns about intellectual autonomy and academic honesty (Le et al., 2025). Whether AI supports or undermines SRC depends largely on how students are instructed to use it. Clear guidelines that delineate acceptable assistance (e.g., brainstorming prompts, language polishing) from academic misconduct (e.g., submitting AI-generated analysis without understanding) enable students to leverage digital tools responsibly, thereby enhancing rather than substituting their research competence.

H4 (+): AI use and academic integrity guidance (AI) is positively associated with SRC.

English Language students confront a "double burden": limited statistical training and the formidable task of producing academic discourse that meets international publication standards (Ciraso-Cali et al., 2022; Le et al., 2023). Within the Theory of Planned Behavior, these barriers reduce perceived behavioral control -- i.e., the learner's belief that they can successfully execute the research task -- which in turn dampens motivation and may constrain final competence. Accordingly, students who perceive greater methodological and linguistic obstacles should, on average, report lower SRC.

H5 (-): Methodological and academic language barriers (MLB) are negatively associated with students' SRC.

Constructive Alignment (Biggs, 1996) stipulates that effective learning requires tight coherence among intended outcomes, instructional activities, and assessment tasks. When applied to a two-course sequence, this principle further demands vertical alignment: the competencies developed in Project 1 should serve as explicit prerequisites for the more demanding tasks of Project 2. A well-articulated progression -- coupled with manageable workload distribution -- enables students to consolidate foundational skills before tackling full-scale research, thereby strengthening SRC.

H6 (+): Course design quality and continuity (AL_CW) is positively associated with SRC.

Group 2: Effects on Satisfaction (SAT) and Overall Effectiveness (OE)

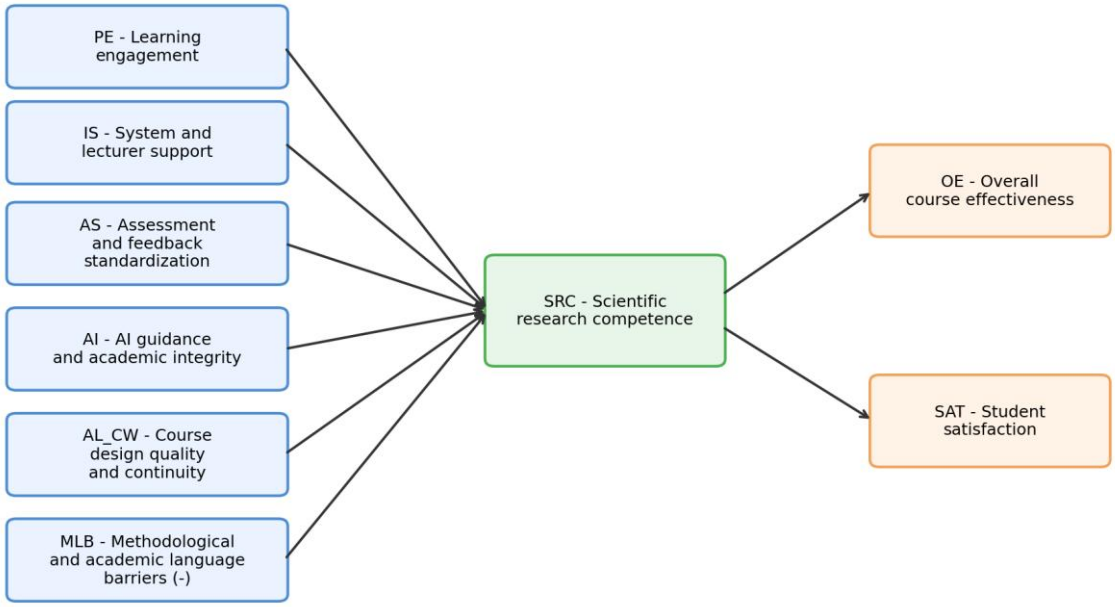
From an Outcome-Based Education perspective, course success is ultimately measured by the competencies that learners acquire. Students who perceive genuine growth in their research capabilities -- from formulating research questions through to interpreting findings and writing academic reports -- are more likely to judge the course as effective and to express satisfaction with their academic investment.

H7 (+): Students' SRC is positively associated with overall course effectiveness (OE).

H8 (+): Students' SRC is positively associated with satisfaction with the course (SAT).

Learner satisfaction is not determined solely by acquired competence; it is also shaped by the quality of the learning experience itself. A curriculum that is logically sequenced, offers appropriate workload, and maintains clear expectations contributes positively to both satisfaction and perceived effectiveness (Reddy & Andrade, 2009). Lecturer and system support create a responsive learning environment, while transparent assessment gives students a sense of procedural fairness and predictability. These institutional factors therefore merit separate paths to the outcome variables:

H9 (+): Course design quality and continuity (AL_CW) is positively associated with student satisfaction (SAT).



H10 (+): System/lecturer support (IS) is positively associated with student satisfaction (SAT).

H11 (+): Course design quality and continuity (AL_CW) is positively associated with overall course effectiveness (OE).

H12 (+): Assessment and feedback standardization (AS) is positively associated with student satisfaction (SAT).

Figure 1

Research model of the proposed effects

3. Methodology

3.1. Research Model and Rationale for Factor Selection

A growing body of evidence suggests that students' SRC is a product not only of individual aptitude but also of the broader academic ecosystem -- including curriculum design, supervisory quality, resource availability, and assessment culture. In the Vietnamese higher-education context, Tinh et al. (2020) identify research awareness, participation motivation, self-assessment capability, and the institutional support environment as key conditions shaping

scientific research capacity. Complementary work on Vietnamese undergraduates further highlights the interplay of university-level encouragement, learning conditions, personal competence, and intrinsic motivation (Bui & Tran, 2022; Son & Mai, 2021; Vo, 2023).

Building on these foundations, the present study constructs an integrated model situating students' self-assessed SRC at the center of a network of six predictor groups -- active learning engagement (PE), lecturer and system support (IS), assessment and feedback standardization (AS), AI use and academic integrity guidance (AI), methodological and academic language barriers (MLB), and course design quality and continuity (AL_CW) - together with two outcome variables: overall course effectiveness (OE) and student satisfaction (SAT). Direct paths from AL_CW, IS, and AS to SAT and OE are also specified. This design permits a simultaneous evaluation of the individual, pedagogical, and institutional factors that may support or constrain SRC development within the two-course Project sequence.

3.2. Research Design

The study employs a convergent mixed-methods design (Creswell & Creswell, 2009). The quantitative strand relies on a structured questionnaire to test the theoretical model and examine hypothesized relationships among the nine latent variables. Concurrently, the qualitative strand draws on semi-structured interviews to elicit richer accounts of students' lived experiences, practical barriers, and perceived support needs across Project 1 and Project 2. Integrating both data sources serves two purposes: it mitigates the inherent limitation of exclusive reliance on self-report measures, and it produces a more complete understanding of the mechanisms through which SRC is developed.

3.3. Research Procedure

Five sequential stages structured the investigation. In the first stage, the researcher reviewed theoretical frameworks (TPB, SRL, Constructive Alignment) and empirical studies to identify the research gap, formulate the structural model, and derive the twelve hypotheses. The second stage involved instrument development: both the quantitative questionnaire and the semi-structured interview guide were drafted, subjected to a pilot survey, and refined to ensure contextual appropriateness for English Language students at HUFLIT. During the third stage, data were collected through a large-scale survey and in-depth interviews conducted simultaneously. In the fourth stage, quantitative data were analyzed in SPSS 26.0 (descriptive statistics, sample profiling) and SmartPLS 4.0 (PLS-SEM, bootstrapping, CTA-PLS), while qualitative transcripts were processed through open, axial, and selective coding in MAXQDA. The fifth and final stage synthesized both datasets, comparing quantitative path results with interview themes to generate conclusions, course-improvement implications, and recommendations for an SRC framework.

3.4. Research Sample and Sampling Method

The quantitative sample comprised 500 English Language students at HUFLIT who had completed both Project 1 and Project 2 - a criterion ensuring that all respondents possessed sufficient learning experience to evaluate course design, support structures, assessment practices, and their own SRC development. Sampling followed a two-stage procedure: convenience sampling was used to identify eligible cohorts, followed by random selection within Project classes to enhance representativeness and meet the requirements of PLS-SEM analysis. For the qualitative component, 19 students were purposively selected to maximize variation in learning outcomes, course experiences, and major orientations.

Regarding demographic composition, female students accounted for 55.2% and male students for 44.8%. Major orientations were distributed as follows: Office Administration (18.0%), Translation and Interpretation (17.6%), English for Logistics (17.6%), Business English (17.2%), English Language Teaching (15.4%), and English-Chinese Bilingual Studies (14.2%). All participants had taken both Project courses, confirming the suitability of the sample for the proposed model.

Table 1

Demographic characteristics of the survey sample

Characteristic	Category	Frequency (n)	Percentage (%)
Gender (GI1)	Male	224	44.8
	Female	276	55.2
Major orientation (GI3)	Translation and Interpretation	88	17.6
	English Language Teaching	77	15.4
	Business English	86	17.2
	English-Chinese Bilingual Studies	71	14.2
	English for Logistics	88	17.6
	Office Administration	90	18.0
Self-assessment of learning outcomes (GI6)	Very good	83	16.6
	Good	103	20.6
	Average	114	22.8
	Somewhat difficult	111	22.2
	Great difficulty	89	17.8

3.5. Scale and Questionnaire Development

The quantitative questionnaire was designed based on the main theories and previous studies, and then adjusted to fit the context of English Language students at HUFLIT. The questionnaire included a demographic information section and a latent-variable scale section using a 5-point Likert scale. The variables in the model included learning engagement (PE), lecturer and system support (IS), assessment and feedback standardization (AS), AI use and academic integrity guidance (AI), methodological and academic language barriers (MLB), course design quality and continuity (AL_CW), self-assessed scientific research competence (SRC), overall course effectiveness (OE), and student satisfaction (SAT).

Self-assessed SRC was measured through core components that reflect the process of conducting an academic study in the English Language context. These components included identifying a research problem and research questions, reviewing the literature, designing the research method and instrument, collecting data, analyzing and interpreting data, writing a research report in academic English, presenting research findings, and cooperating during the

project. This variable reflects how students evaluate their own competence after completing Project 1 and Project 2. Meanwhile, AI use and academic integrity guidance (AI) was treated as a separate independent variable to avoid conceptual overlap with SRC.

For qualitative data, the semi-structured interview guide was developed around key themes, including learning experiences, methodological/language barriers, the role of supervisors, the usefulness of rubrics, AI use in academic work, and suggestions for course improvement.

3.6. Data Collection Method

Quantitative data were collected through Google Forms and distributed directly in classes as well as through internal learning channels of English Language students. The survey was conducted after students had completed both Project courses to ensure that participants had enough experience to evaluate them. Qualitative data were collected through face-to-face or online interviews, with an average duration of 20 to 30 minutes for each student. The interviews were recorded with participants' consent and transcribed into text for analysis.

3.7. Data Analysis Method

Quantitative data were first processed using SPSS 26.0 for descriptive statistics of the survey sample. Then, SmartPLS 4.0 was used to analyze the partial least squares structural equation model (PLS-SEM). The measurement model was assessed through internal consistency reliability, convergent validity, and discriminant validity. Reliability was examined using Cronbach's alpha, rho_A, and Composite Reliability, with the accepted threshold above 0.70. Convergent validity was assessed using factor loading and Average Variance Extracted (AVE). In principle, factor loading should be about 0.70 or higher. Indicators close to 0.70 may be retained if Composite Reliability and AVE meet the required level. AVE should be 0.50 or higher.

Discriminant validity of the measurement model was assessed using the Fornell-Larcker and HTMT criteria. According to the Fornell-Larcker criterion, the square root of the AVE of each latent variable must be higher than its correlations with the other latent variables. In addition, the HTMT ratio (Heterotrait-Monotrait Ratio), following Henseler et al. (2014), was used to test the level of distinction among concepts in the model. An HTMT value below 0.85 is considered acceptable at a strict level, while the 0.90 threshold may be accepted for closely related concepts. Using both criteria helps ensure that the variables in the measurement model are conceptually different before the structural model is analyzed.

The structural model was assessed using the collinearity coefficient VIF, the coefficient of determination R-squared, the effect size f-squared, the predictive relevance Q-squared, and hypothesis testing with bootstrapping using 5,000 subsamples. A hypothesis was supported when the path coefficient was statistically significant with p-value < 0.05 and t-statistics > 1.96. Because the study used cross-sectional and self-reported data, the structural paths were interpreted as predictive relationships rather than definitive causal effects. Qualitative data were analyzed through thematic analysis with the support of MAXQDA. This included open coding, axial coding, and selective coding to identify themes corresponding to the variables in the model.

3.8. Research Ethics

The study followed ethical principles in educational research. All participants were informed about the purpose and scope of the study and their right to withdraw at any time without any effect on their learning results. The collected data were used only for academic

purposes. Personal information was anonymized and coded. Citation, data processing, and result reporting were conducted honestly and followed the rules of academic integrity and intellectual property.

4. Results

4.1. Self-assessment of learning outcomes

Table 2 presents students' self-assessment of their learning outcomes after taking Project 1 and Project 2. The results show that the group rating themselves as Average had the highest proportion at 22.8%, followed by the Somewhat difficult group at 22.2%. Meanwhile, 20.6% of students rated their outcomes as Good, 16.6% as Very good, and 17.8% stated that they experienced Great difficulty. This distribution shows that the two Project courses set considerable academic demands for students, especially because they had to combine research skills, data processing, and academic English competence.

Table 2

Self-assessment of learning outcomes

Self-assessment of learning outcomes	Frequency (n)	Percentage (%)
Very good	83	16.6
Good	103	20.6
Average	114	22.8
Somewhat difficult	111	22.2
Great difficulty	89	17.8
Total	500	100.0

4.2. Measurement Model Evaluation

The measurement model was assessed to ensure that the observed variables properly reflected the concepts being measured, or the latent variables. The assessment included reliability, convergent validity, and discriminant validity.

4.2.1. Construct Reliability and Convergent Validity

According to Hair et al. (2019), scale reliability is assessed through Cronbach's Alpha, rho_A, and Composite Reliability (CR), with an accepted threshold of > 0.70. Convergent validity is assessed through factor loading and Average Variance Extracted (AVE), in which AVE should be 0.50 or higher.

Table 3

Results of construct reliability and convergent validity assessment

Latent variable	Cronbach's alpha	rho_a	rho_c	Average Variance Extracted (AVE)	Factor Loading
AI	0.859	0.863	0.905	0.704	.814 - .874
AL_CW	0.943	0.946	0.951	0.663	.758 - .877
AS	0.926	0.928	0.940	0.692	.791 - .881

IS	0.894	0.900	0.922	0.703	.784 - .864
MLB	0.959	0.967	0.964	0.689	.765 - .867
OE	0.901	0.905	0.927	0.718	.808 - .883
PE	0.913	0.915	0.932	0.697	.784 - .865
SAT	0.897	0.897	0.924	0.708	.820 - .865
SRC	0.978	0.978	0.979	0.652	.753 - .876

Based on Table 3, all scales achieved excellent reliability and convergent validity. Cronbach's alpha, rho_A, and rho_C values of all variables were well above the 0.70 threshold, indicating strong internal consistency among the items. Furthermore, the AVE values of all variables exceeded the 0.50 benchmark, ranging from 0.652 to 0.718. The factor loadings presented in the table demonstrate that the observed items effectively reflected their corresponding latent concepts. Therefore, the measurement model robustly met the requirements for further testing of discriminant validity and structural relationships.

4.2.2. Discriminant Validity

Discriminant validity was tested to ensure that the latent variables in the model were conceptually distinct from one another. The results based on the Fornell-Larcker and HTMT criteria are presented in Table 4 and Table 5.

Table 4

Discriminant validity results based on the Fornell-Larcker criterion

	AI	**AL_CW**	**AS**	**IS**	**MLB**	**OE**	**PE**	**SAT**	**SRC**
AI	0.839								
AL_CW	0.501	0.814							
AS	0.494	0.508	0.832						
IS	0.448	0.448	0.480	0.838					
MLB	0.203	0.129	0.147	0.118	0.830				
OE	0.480	0.479	0.537	0.530	0.098	0.847			
PE	0.521	0.527	0.562	0.601	0.153	0.564	0.835		
SAT	0.478	0.479	0.552	0.549	0.108	0.535	0.616	0.842	
SRC	0.499	0.546	0.587	0.537	0.143	0.581	0.632	0.571	0.808

Table 5

Discriminant validity results based on the HTMT ratio (Heterotrait-Monotrait Ratio)

	AI	**AL_CW**	**AS**	**IS**	**MLB**	**OE**	**PE**	**SAT**	**SRC**
AI									
AL_CW	0.554								
AS	0.554	0.542							

IS	0.509	0.486	0.523					
MLB	0.223	0.133	0.153	0.125				
OE	0.544	0.517	0.583	0.587	0.102			
PE	0.587	0.567	0.609	0.664	0.162	0.620		
SAT	0.542	0.519	0.605	0.609	0.116	0.593	0.680	
SRC	0.541	0.567	0.615	0.570	0.142	0.616	0.667	0.608

The discriminant validity results demonstrate that the measurement model successfully met the requirements of both the Fornell-Larcker and HTMT criteria. Specifically, under the Fornell-Larcker criterion, the square root of the AVE of each latent variable (the diagonal values in Table 4) was strictly higher than its correlations with all other variables. More importantly, all HTMT values in Table 5 were well below the stringent 0.85 threshold, with the highest recorded value being just 0.680 (between PE and SAT). This indicates excellent discriminant validity, ensuring that the constructs within the model are empirically distinct and highly suitable for structural equation modeling.

4.2.3. Confirmatory Tetrad Analysis (CTA-PLS)

Traditionally, the decision to set scales as Reflective or Formative is often based only on theoretical arguments. However, to avoid measurement model misspecification, this study conducted Confirmatory Tetrad Analysis (CTA-PLS) to use empirical data to confirm whether the scales used in the study were reflective or formative (Hair et al., 2019).

CTA-PLS tests the statistical significance of tetrads, which are differences between products of covariances of pairs of observed variables. The evaluation criteria are based on the p-value and confidence interval from the bootstrapping procedure. If p-value > 0.05 or the 95% confidence interval includes 0, the study does not have enough evidence to reject the assumption that the scale is reflective. In contrast, if p-value < 0.05 and the confidence interval does not include 0, the scale should be reconsidered as formative.

The SmartPLS results show that, for latent variables with four or more observed variables in the model, the tetrads were generally not statistically significant and the adjusted confidence intervals (CI adjusted) all included 0. This result shows that the empirical data did not reject the reflective specification of the scales in the model.

This result supports the use of reflective scales in the study. It is consistent with the original theoretical basis from the Theory of Planned Behavior (TPB), Self-Regulated Learning (SRL), and the way the model concepts were measured.

4.3. Structural Model Evaluation and Hypothesis Testing

After the measurement model was confirmed, the structural model was analyzed to test the research hypotheses through the bootstrapping algorithm with 5,000 subsamples.

4.3.1. Collinearity Issues

Before testing the effects, the inner VIF was examined to ensure that there was no collinearity problem among the independent variables. Table 5 presents the VIF results.

Table 6

Collinearity test results (VIF)

Independent variable	OE	SAT	SRC
AI			1.638
AL_CW	1.426	1.586	1.641
AS		1.716	1.718
IS		1.532	1.697
MLB			1.048
PE			2.048
SRC	1.426	1.910	

As shown in Table 6, all inner VIF values across the structural model ranged from 1.048 to 2.048. These values are consistently well below the conservative threshold of 3.0 (and far below the maximum acceptable limit of 5.0 set by Hair et al., 2019). This confirms that multi-collinearity was not a problem and did not bias the estimation of the path coefficients.

4.3.2. Explanatory Power (R^2) and Effect Size (f^2)

- R^2 coefficient: This shows the level of variance in the dependent variables (OE, SAT, SRC) explained by the independent variables.
- f^2 coefficient: This evaluates the contribution level, large, medium, or small, of each independent variable to the dependent variable.

Table 7

Explanatory power (R^2) of the model

Dependent variable	R^2	Adjusted R^2
OE	0.375	0.372
SAT	0.460	0.455
SRC	0.527	0.521

Table 8

Effect size (f^2) of the independent variables

Independent variable	OE	SAT	SRC
AI			0.010
AL_CW	0.059	0.017	0.039
AS		0.058	0.065
IS		0.082	0.024
MLB			0.000
PE			0.081

SRC	0.233	0.051

Explanatory power (R-squared): The predictor variables in the model explained 52.7% (R-squared = 0.527) of the variance in Scientific Research Competence (SRC). In educational and behavioral research, this represents a highly satisfactory and realistic level of explanatory power, indicating that the proposed framework comprehensively captures the core factors associated with SRC development. Concurrently, the structural model successfully explained 37.5% of the variance in overall course effectiveness (OE) and 46.0% of the variance in student satisfaction (SAT).

- Effect size (f^2):

  - Among the factors predicting SRC, learning engagement (PE) was the largest contributor with an effect size of $f^2 = 0.081$, representing a small-to-medium meaningful effect.

  - SRC exhibited a medium effect on overall course effectiveness (OE), with $f^2 = 0.233$.

  - Notably, methodological and academic language barriers (MLB) had no practical effect on SRC ($f^2 = 0.000$), which directly aligns with the non-significant outcome observed for hypothesis H5.

4.3.3. Hypothesis Testing

The strength of association between variables was assessed through the path coefficient (beta), t-statistics, and p-value obtained from the bootstrapping process. A hypothesis was accepted when p-value < 0.05 and t-statistics > 1.96.

Table 9

Hypothesis testing results (Bootstrapping)

Hypothesis	Path	Original sample (O)	Mean (M)	Standard deviation (STDEV)	*t* statistics	*p* values	Conclusion
H1	PE -> SRC	0.279	0.281	0.042	6.627	<.001	Accepted
H2	IS -> SRC	0.140	0.140	0.041	3.442	.001	Accepted
H3	AS -> SRC	0.229	0.228	0.039	5.856	<.001	Accepted
H4	AI -> SRC	0.089	0.088	0.041	2.172	.030	Accepted
H5	MLB -> SRC	0.010	0.014	0.028	0.342	.733	Rejected
H6	AL_CW -> SRC	0.174	0.174	0.043	4.057	<.001	Accepted
H7	SRC -> OE	0.455	0.456	0.036	12.512	<.001	Accepted
H8	SRC -> SAT	0.229	0.229	0.043	5.381	<.001	Accepted
H9	AL_CW -> SAT	0.119	0.119	0.043	2.796	.005	Accepted
H10	IS -> SAT	0.261	0.261	0.042	6.237	<.001	Accepted
H11	AL_CW -> OE	0.230	0.230	0.039	5.860	<.001	Accepted
H12	AS -> SAT	0.232	0.233	0.041	5.667	<.001	Accepted

The bootstrapping results reveal that the proposed research model was robustly supported by the empirical data. Among the factors associated with scientific research competence (SRC), active learning engagement (PE) emerged as the strongest predictor (β = 0.279, $p < .001$), followed by assessment and feedback standardization (AS) (β = 0.229, $p <$ .001), course design quality and continuity (AL_CW) (β = 0.174, $p < .001$), and system and lecturer support (IS) (β = 0.140, $p = .001$). Meanwhile, AI use guidance linked with academic integrity (AI) was a statistically significant but relatively weak predictor of self-assessed SRC

(β = 0.089, p = .030, f^2 = 0.010). These findings suggest that the development of students' SRC relies not only on individual effort but also heavily on transparent assessment rubrics, logical curriculum sequencing, academic scaffolding, and institutional regulations regarding digital tools.

Crucially, Hypothesis H5, which predicted a negative relationship between methodological and academic language barriers (MLB) and SRC, was not supported. The relationship was found to be exceptionally weak and statistically non-significant (β = 0.010, t = 0.342, p = .733). In addition, SRC was positively and strongly associated with overall course effectiveness (OE) and student satisfaction (SAT). Moreover, institutional factors such as AL_CW, IS, and AS were also significantly related to the outcome variables, emphasizing the pivotal role of curriculum design, supervisory support, and assessment standardization in shaping the overall learning experience across the Project 1 and Project 2 sequence.

4.4. Summary of Quantitative Analysis Results

Table 9 summarizes the hypothesis testing results for the structural model. Out of the 12 proposed hypotheses, 11 were strongly supported by the empirical data ($p < .05$), confirming the theoretical validity and robustness of the model. The sole exception was H5, whose rejection provides vital nuances regarding students' coping behaviors, a phenomenon further explored through the qualitative findings.

4.5. Qualitative Data Analysis Results (In-depth Interviews)

To complement the quantitative findings, the study analyzed 19 semi-structured interviews. The thematic analysis was used to clarify how students experienced Project 1 and Project 2, why some relationships in the quantitative model appeared as they did, and what kinds of support students considered necessary for improving scientific research competence.

Overall, students described the Project sequence as academically valuable but mentally demanding. Most participants considered Project 2 more challenging than Project 1 because it required deeper methodological application, stronger theoretical reasoning, and more careful interpretation of research findings. Project 1 was often viewed as a starting framework that introduced students to questionnaire design, basic data collection, and the general structure of a research paper. However, several participants also reported that the connection between the two courses was not always smooth. Instead of developing into a clearly progressive learning sequence, Project 2 was sometimes perceived as repeating the structure of Project 1 with more detailed requirements. The transition from data collection to data analysis was especially difficult because students felt that they had not received enough preparation in SPSS or quantitative interpretation before being required to analyze and discuss results.

The interviews also showed that students developed certain aspects of SRC after completing the two courses, especially in searching for materials, designing questionnaires, organizing group work, and presenting research results. Nevertheless, their competence development was uneven. The most frequently mentioned bottlenecks were the Literature Review, Findings/Data Analysis, and Discussion sections. Students found it difficult to locate suitable academic sources, synthesize previous studies, identify a research gap, and transform statistical results into meaningful arguments. These difficulties were not only methodological but also linguistic. Many students reported that they had ideas but struggled to express them in an academic English style, paraphrase appropriately, and follow APA conventions. This confirms the "double burden" experienced by English Language students, who must learn both research methodology and academic language at the same time.

Several learning conditions helped explain why students' SRC varied across individuals and groups. Students who actively monitored deadlines, divided tasks clearly, searched for additional learning materials, and communicated regularly with teammates tended to understand the research process more deeply. Lecturer support also played an important role. Participants valued step-by-step guidance, direct correction, and specific formative feedback because these helped them recognize what was wrong and how to revise their work. In contrast, delayed or overly general comments made students feel uncertain and increased pressure. Teamwork was another influential factor. While a balanced and responsible group could reduce workload and support learning, unequal participation and free-rider behavior placed heavy pressure on group leaders and sometimes allowed less active members to pass the course without developing equivalent research competence.

The qualitative data also helped explain the unexpected quantitative result for methodological and academic language barriers (MLB). Although students described these barriers as serious, MLB did not show the hypothesized negative relationship with SRC in the structural model. One possible explanation is that the MLB scale may have captured students' awareness of research difficulties rather than only the actual obstructive level of those difficulties. Students with stronger research competence may be more capable of recognizing that Literature Review writing, SPSS analysis, and Discussion writing are difficult tasks. Therefore, they may report both higher SRC and higher awareness of barriers. In addition, students often used coping strategies to reduce the visible impact of barriers on their self-assessed competence. These strategies included relying on more capable group members, using templates or previous papers, and using AI tools for language support, idea generation, and data interpretation. As a result, the barriers remained important in students' lived experiences, but their direct negative association with SRC was not statistically confirmed.

AI use was common among the interviewed students. Participants reported using tools such as ChatGPT, Gemini, Claude, Grammarly, and QuillBot for brainstorming, grammar checking, paraphrasing, translation, summarizing documents, and sometimes interpreting data. Many students were able to distinguish between supportive and problematic AI use. They considered AI acceptable when it helped suggest ideas, check language, or clarify difficult concepts, but they regarded copying AI-generated content without understanding as a violation of academic integrity. However, because course-level AI guidelines were still unclear, students were unsure about the acceptable boundary of AI use. Under deadline pressure, some students admitted that AI could become a shortcut rather than a learning support tool, especially in writing the Findings and Discussion sections. This suggests that AI literacy and academic integrity guidance should be integrated more explicitly into the Project courses.

Finally, students' suggestions focused mainly on course design, learning materials, and feedback. Although the semester length of three to four months was considered generally sufficient for group work, the amount of knowledge was perceived as heavy and highly concentrated. Students expressed a strong need for sample papers, chapter checklists, templates, APA guidance, and clearer instructions on SPSS. Moodle was seen mainly as a submission platform rather than a learning resource repository. Participants suggested that Project 1 and Project 2 should be more clearly differentiated: Project 1 should focus on foundational research skills such as reading articles, identifying gaps, designing instruments, and practicing basic data analysis, while Project 2 should focus on applying those skills in a complete research paper. They also emphasized the need for timely, detailed, and constructive lecturer feedback throughout the course rather than only at the final submission stage.

5. Discussion

5.1. Discussion on the Scientific Research Competence of English Language Students

The mixed-methods findings show a multi-dimensional picture of HUFLIT students' SRC. Quantitatively, the self-assessment results were not concentrated only in the high group: 37.2% of students rated themselves as Good/Very good, while the remaining 62.8% were in the Average, Somewhat difficult, or Great difficulty groups. The qualitative data further explained the gap between perceived competence and real difficulties during the Project process.

In practice, students were often more confident in surface-level tasks such as basic literature searching, designing Google Form questionnaires, or making PowerPoint presentations. When they had to work on core tasks such as writing the Literature Review, analyzing data with SPSS, and writing the Discussion, many students admitted that they were confused and lacked direction. This gap may come from the fact that some students passed the course because of strong support from group leaders, unequal task division in groups, or heavy reliance on generative AI tools.

This reflects the "double burden" faced by English Language students (Ciraso-Cali et al., 2022; Le et al., 2023). They not only lack a strong background in statistical thinking, or the logic of quantitative data analysis, but are also limited by academic English when they need to paraphrase and argue according to international academic standards.

5.2. Discussion on Factors Associated with SRC

The structural model (PLS-SEM) supported 11 out of 12 research hypotheses. Because the study used cross-sectional self-report data, the following discussion interprets the paths as predictive relationships and associations rather than definitive causal effects. The combination of quantitative and qualitative data provides deeper explanations for these relationships.

5.2.1. The key role of learning engagement (PE) and lecturer support (IS).

The statistical results confirm that learning engagement (PE) was the strongest predictor of SRC (H1). The interview data reinforce this finding: students who actively monitored their progress, learned tools by themselves, and communicated well with their groups tended to develop a deeper understanding of the course. In addition, lecturer support (IS) worked as cognitive scaffolding. Lecturers who directly corrected students' work and provided detailed formative feedback helped students shape their research thinking, which is consistent with Self-Regulated Learning (Panadero & Broadbent, 2018).

5.2.2. The importance of assessment standardization (AS) and course design quality and continuity (AL_CW).

The study shows that rubrics and assessment transparency (AS) were positively related to students' competence and satisfaction. However, the qualitative data reveal a tension that deserves closer scrutiny from a curricular-design perspective. While the course sequence ostensibly follows a progressive model - Project 1 for data collection, Project 2 for methodology and full-report writing - the actual student experience suggests a structural misalignment that the current implementation has not resolved.

Specifically, students are required to produce a complete research report in Project 1, yet the statistical and methodological tools they need (particularly SPSS-based data analysis) are introduced substantively only in Project 2. This sequencing creates what Biggs (1996) would characterize as a failure of constructive alignment: the assessment task (a full report)

outpaces the instructional preparation. The consequence is predictable - students resort to compensatory strategies such as template reproduction, peer dependence, or AI-assisted writing to bridge the competence gap, rather than developing the intended research skills organically. In effect, the curriculum asks students to demonstrate competencies it has not yet taught.

This structural deficiency is not merely a scheduling inconvenience; it undermines the pedagogical rationale of the two-course sequence. If Project 1 is meant to build foundational skills, its assessment should be calibrated accordingly - focusing, for example, on instrument design, pilot data collection, and literature review drafting, rather than demanding a complete manuscript. Project 2 would then function as the integrative course where students apply the full research cycle, including data analysis and discussion writing, supported by explicit SPSS instruction introduced earlier or concurrently. The department's current arrangement, where the most analytically demanding assessment precedes the corresponding instruction, not only overloads students but also dilutes the diagnostic value of Project 1 grades as indicators of genuine research readiness.

5.2.3. The unexpected result of methodological and language barriers (MLB).

One of the more noteworthy findings of this study is the rejection of H5. The quantitative data show that methodological and academic language barriers (MLB) had a positive but statistically non-significant relationship with SRC ($\beta = 0.010$, $t = 0.342$, $p = .733$), even though the hypothesis predicted a negative relationship and the interview data clearly documented students' struggles with academic English, research methods, and data analysis.

This anomaly warrants careful methodological reflection rather than superficial dismissal. The most parsimonious explanation lies in a construct-measurement problem: the MLB scale, as operationalized, appears to tap into perceived difficulty awareness rather than actual obstructive impact. These are conceptually distinct constructs. A student with strong research competence may be more cognizant of the inherent challenges of SPSS analysis and academic writing precisely because they have engaged deeply enough with these tasks to appreciate their complexity. Conversely, a student who has relied heavily on group leaders or AI tools may report fewer barriers simply because they have not confronted them directly. The result is a paradoxical positive association - or, at best, a null one - between barrier perception and competence.

This interpretation is corroborated by the qualitative data. Students frequently described coping mechanisms - including delegation to more capable group members, reliance on AI-generated text, and reproduction of report templates - that effectively attenuated the impact of barriers on self-assessed SRC without eliminating the barriers themselves from the learning experience. In other words, the barriers remained real and substantial in students' narratives, but the compensatory behaviors severed the expected negative link to competence outcomes.

Future research should address this measurement limitation by distinguishing between two dimensions of barrier experience: (a) awareness (the extent to which students recognize methodological and linguistic challenges) and (b) obstruction (the degree to which those challenges actually impede research performance). A two-factor operationalization of MLB would likely produce a clearer - and theoretically consistent - picture of the barrier-competence relationship. This should be treated as a design limitation of the current study rather than evidence that barriers are unrelated to SRC.

5.3. Discussion on Artificial Intelligence (AI) and Academic Integrity

In the context of wide AI use in learning, this study views AI guidance and academic integrity as a construct that can positively contribute to SRC (H4) when managed through explicit institutional protocols. Interviews reveal that most students used AI in some capacity during their Project courses. When AI was deployed for legitimate purposes - brainstorming, grammar correction, structural suggestions - it helped students mitigate part of the linguistic burden that characterizes the EFL research context.

However, the boundary of integrity is becoming increasingly blurred in the absence of clear, course-level guidelines. Some students admitted that they relied too heavily on AI to write or explain content, especially in the Findings and Discussion sections, where original analytical reasoning is most critical. This creates risks on two fronts: first, the ethical risk of academic dishonesty; and second, the pedagogical risk that AI dependence replaces - rather than scaffolds - the development of critical thinking. The Project courses therefore need a formal and explicit set of AI use regulations, integrated into both the syllabus and the assessment rubric, so that students can deploy digital tools as support mechanisms rather than substitutes for the research thinking process.

6. Conclusion

6.1. General Conclusion of the Study

This study was conducted to evaluate the scientific research competence (SRC) of English Language students at HUFLIT through Project 1 and Project 2, and then propose a competence framework and improvement solutions. By applying a convergent mixed-methods design, combining PLS-SEM for 500 quantitative responses and thematic analysis for 19 semi-structured interviews, the study answered the initial research questions. Because the data were cross-sectional and self-reported, the findings should be understood as evidence of associations and predictive relationships rather than definitive causal effects.

The findings show that students' SRC developed through the two courses but not evenly. Positive progress was found in literature searching, questionnaire design, and basic academic thinking. However, major bottlenecks remained in quantitative data analysis using SPSS, argument writing in the Discussion section, and academic English.

Regarding the associated factors, the quantitative data show that 11 out of 12 hypotheses were supported. Active learning engagement (PE), course design quality and continuity (AL_CW), lecturer/system support (IS), assessment and feedback standardization (AS), and AI use guidance linked with academic integrity (AI) were positively associated with SRC. Among them, PE was the strongest predictor of SRC ($\beta = 0.279$, $p < .001$). In contrast, methodological and academic language barriers (MLB) showed a positive but statistically non-significant relationship with SRC ($\beta = 0.010$, $t = 0.342$, $p = .733$), although students still described them as important difficulties in interviews. This suggests that MLB may reflect students' awareness of difficulty and their coping strategies, not only the actual obstructive power of those barriers. In addition, SRC was positively associated with overall course effectiveness (OE) and satisfaction (SAT), confirming the central role of SRC in the course experience.

6.2. Proposed SRC Framework for English Language Students

Based on the theoretical foundation, course learning outcomes (CLOs), and practical findings at HUFLIT, the study proposes a Scientific Research Competence framework for English Language students. It includes five core competence groups:

1. Methodological Competence: The ability to identify a research gap related to linguistics, teaching methods, translation, or culture, and to choose a suitable research design, such as qualitative, quantitative, or mixed methods.

2. Academic Linguistic Competence: The ability to read and synthesize specialized English materials, use standard academic writing style, paraphrase appropriately, and follow citation rules strictly, such as APA 7th edition.

3. Data Analysis Competence: The ability to design unbiased questionnaires/interview questions, use software such as Excel and basic SPSS to process data, and interpret statistical results into logical arguments.

4. Collaborative and Managerial Competence: The ability to plan and manage the research timeline in a scientific way, communicate effectively, solve group conflicts, and reduce free-rider behavior.

5. Digital Integrity and AI Literacy: The ability to search reliable academic databases and use generative AI responsibly: using AI to support idea generation and grammar correction, but never misusing it to fake analytical arguments or plagiarize.

6.3. Recommendations for Improvement

Based on the findings and the proposed competence framework, the study offers the following solutions to improve the quality of the two Project courses:

For the Faculty and the University (course design improvement):

- Reposition the goals of Project 1 and Project 2: Reduce the overlap in requirements between the two courses. Project 1 should be structured mainly as a skills course, focusing on how to read articles, write a Literature Review, design questionnaires, and practice basic SPSS/Excel. Project 2 should be the application course in which students conduct a complete research paper.
- Issue "Guidelines for AI Use in Academic Work": Clear regulations should be provided in writing and in the rubric about the boundary between AI "support" and "plagiarism". Tasks should also require students to submit a prompt log to show their independent thinking.
- Build a shared learning material repository (LMS/Moodle): Moodle should be improved by providing standard templates, chapter checklists, and an APA handbook so that students can self-study more easily and reduce complete dependence on supervisors.

For supervisors:

- Strengthen formative assessment: Instead of only using final summative assessment, lecturers should create small submission milestones to provide timely feedback. Feedback should be constructive and show students how to revise, not only say whether something is right or wrong.
- Manage teamwork strictly: Groups should be required to prepare a clear Task Assignment Log from the beginning of the semester. An anonymous peer-assessment mechanism should be applied at the end of the course to individualize scores, ensure fairness, and reduce free-rider behavior.

For students:

- Students should improve their self-regulation and actively plan their research from the beginning of the semester instead of waiting until the deadline is very close.
- Students should strictly follow academic integrity principles and view scientific research as an opportunity to develop analytical thinking and critical thinking skills that directly support their future work and career development.

6.4. Limitations and Directions for Future Research

Although the study tried to ensure objectivity and scientific quality, it still has several limitations. First, the study was conducted at only one institution, Ho Chi Minh City University of Foreign Languages - Information Technology. Therefore, the generalizability of the findings to other universities with similar programs should be considered carefully. Second, the study used a cross-sectional design, reflecting students' competence at one point after they completed Project 1 and Project 2. It did not assess longitudinal changes in competence throughout the learning process. Third, the SRC variable was mainly measured through students' self-assessment. Therefore, future studies should include evidence from learning products, rubric scores, or independent lecturer assessment to verify actual competence. Fourth, as discussed in Section 5.2, the MLB construct may have conflated awareness of difficulty with actual obstruction by difficulty. Future research should operationalize these as separate sub-dimensions to more accurately capture the barrier-competence relationship and produce findings consistent with established theory (Ciraso-Cali et al., 2022; Le et al., 2023). Finally, because all quantitative variables were collected through the same survey, common method bias may still have influenced the observed relationships, even though the model showed acceptable reliability and validity.

In the future, further studies can expand the sample to different universities to increase representativeness. In addition, using an experimental design to directly test the effectiveness of applying the SRC framework, AI guidance handbook, or peer-review process in Project classes would provide more valuable and practical contributions to the teaching of scientific research methodology in Vietnam.

Tran Nhu Uyen Le[1], Diem Bich Huyen Bui[2]

Abstract

The ability to construct well-supported arguments, address counterarguments, and provide effective refutations is essential in an argumentative essay. Despite increasing access to digital writing support tools, many English-majored students still struggle to produce well-developed argumentative essays. However, there is limited research on how students use ChatGPT to support argumentative writing and how they perceive its effectiveness. This study, therefore, investigates how 10 intermediate-level English majors use ChatGPT to support their argumentative writing through a qualitative design. The qualitative data revealed both positive and negative perspectives. On the one hand, ChatGPT was reported to play a supportive role in helping students strengthen their arguments by offering various argument options with relevant supporting details and evidence when prompted and reprompted correctly, and develop evaluative judgment to assess the effectiveness of the response and research skills to confirm the knowledge. It also supported students during the feedback stage by providing suggestions on language use and explanations of failures related to idea development, cohesion, and coherence in their writing. On the other hand, some students expressed concerns that without a clear understanding of ethical use and underlying cognitive processes, they may become overly reliant on the AI tool. Others reported limited prompting literacy and highlighted the need to develop this strategy to obtain more meaningful responses in a shorter time. These findings suggest that while AI tools can be helpful in improving argumentative writing, students still need guidance and should use them carefully to continue developing their own thinking and writing skills independently.

***Keywords*:** AI-assisted learning, argumentative writing, ChatGPT, writing support tool

1. Introduction

Argumentative writing is a central skill in English as a Foreign Language (EFL) academic contexts because it requires not only language accuracy but also higher-order abilities such as idea generation, logical reasoning, supporting claims with appropriate evidence, and engaging with counterarguments effectively (Song & Song, 2023). Research on academic writing has shown that EFL students often face difficulty with not only these aspects, but also other linguistic problems such as grammar, vocabulary, and organization (Sarıça & Gençoğlu, 2025). These can affect the quality of argumentative essays and lead to students' writing anxiety and low confidence (Song & Song, 2023). Oh and Hsieh (2025) also found that students' argumentative essays often contain vague thesis statements, underdeveloped arguments, insufficient evidence, weak transitions, unclear counterarguments, and grammatical inaccuracies. Given the challenges of argumentative writing and its crucial role in academic achievement, finding effective ways to support EFL learners in developing this essay genre is important in writing instruction.

The rapid growth of artificial intelligence (AI) has provided opportunities for language learning. Among these, ChatGPT has attracted increasing attention because of its ability to generate text, provide instant feedback, rephrase ideas, and support students in improving their writing (Song & Song, 2023). Research suggests that when integrated into learning activities, ChatGPT can positively contribute to students' writing development, organization, and confidence in their writing abilities (Faiz et al., 2023). These features show that ChatGPT can support learners not only with language use but also with organizing and developing ideas in argumentative writing.

Despite these aforementioned benefits, there are still some challenges when using ChatGPT as a supporting tool for writing. Some studies suggest that AI tools may help students improve grammar and vocabulary, but these improvements are often limited to the surface level. Students may not engage deeply with critical thinking or argumentative reasoning, especially when instructional support is limited (Mai, 2026). Another concern is that students may rely too heavily on AI-generated suggestions without carefully evaluating the content. This can reduce learner autonomy and limit the development of original ideas (Sarıça & Gençoğlu, 2025). In addition, effective use of ChatGPT requires prompting literacy. Students need to write clear prompts, evaluate AI responses, and revise their queries when necessary. However, many learners have not yet fully developed these skills.

Although research on AI-assisted writing has grown rapidly, most of the existing literature has focused on writing outcomes, language accuracy, or general attitudes toward AI use. There is limited qualitative research on EFL students' perceptions of the usefulness and concerns of using ChatGPT for argumentative writing, especially in the Vietnamese higher education context. To address this gap, the present study investigates how intermediate-level English-major students perceive the benefits and challenges of using ChatGPT to support the writing of argumentative essays, based on participants' authentic practices and experiences. The findings are expected to contribute to EFL writing pedagogy by identifying both the advantages and potential difficulties of ChatGPT-supported argumentative writing. To fulfill this objective, the study seeks to answer the following research question*: How do EFL students perceive ChatGPT's role in supporting argumentative essay writing?*

2. Literature Review

2.1. Argumentative writing and its aspects

2.1.1. Argumentative writing

Argumentative writing is an important academic skill in higher education. It helps students not only demonstrate their language proficiency but also develop critical thinking, reasoning, and academic literacy (Ekalia et al., 2025). Ho et al. (2024) state that writing argumentative essays is demanding for EFL students because it requires language knowledge, idea generation, organization, grammar, vocabulary, mechanics, and writing style. Writers are also expected to consider and respond to opposing viewpoints in order to build a convincing argument (Walková & Bradfrod, 2022). For EFL students, this type of writing can be particularly challenging because they must manage both language use and argument development at the same time (Ekalia et al., 2025). As Ho et al. (2024) note, effective argumentative writing involves making a clear claim, providing supporting evidence, and addressing counterarguments to persuade readers.

2.1.2. Aspects of argumentative writing

One important aspect of argumentative writing is the development of a clear and arguable claim. The claim represents the writer's position on an issue and guides the overall direction of the essay. Effective argumentative writing requires students to address opposing viewpoints and provide rebuttals. According to Oh and Hsieh (2025), argumentative essays require students to present a clear thesis, develop supporting arguments, consider opposing views, and provide rebuttals. Similarly, Tai et al. (2025) and Darmawansah et al. (2024) highlight the importance of counterarguments and rebuttals in constructing strong arguments.

Another key aspect of argumentative writing is the use of evidence and reasoning. Effective arguments are supported by relevant facts, examples, and explanations rather than personal opinions alone. Evidence helps support the writer's claim, while reasoning explains how the evidence relates to the argument. Wang et al. (2024) note that strong arguments include elements such as claims, evidence, reasoning, and rebuttals. Besides, argumentative writing also requires critical thinking. Students need to analyze information, evaluate evidence, compare different viewpoints, and draw reasoned conclusions. As Suh et al. (2025) and Chen et al. (2025) suggest, argumentative writing and critical thinking are closely connected because students must examine information carefully and justify their positions with logical support.

Organization and coherence are also essential in argumentative writing. Ideas should be presented in a logical order and connected clearly throughout the essay. A typical argumentative essay includes an introduction that presents the issue and thesis statement, body paragraphs that develop arguments with evidence and reasoning, and a conclusion that emphasizes the writer's position. Tai et al. (2025) note that effective argumentation depends on both clear structure and appropriate language features, such as transitions and conclusion markers. These elements help readers follow and understand the argument more easily.

2. ChatGPT in supporting argumentative writing

Research suggests that EFL students use ChatGPT for brainstorming, organizing ideas, drafting, and revising their essays (Ho et al., 2024). Many students perceive ChatGPT as a helpful resource because it provides quick access to information, expands vocabulary, and assists with essay organization (Esmaeil et al., 2023; Annamalai et al., 2025). These features may help learners overcome difficulties in generating and developing arguments.

In argumentative writing, ChatGPT can also support the development of essay structure, counterarguments, and feedback. Studies have shown that students use ChatGPT to create outlines, organize arguments, and improve the coherence of their essays (Pratama et al., 2025). In addition, ChatGPT can provide immediate feedback on issues such as thesis statements, argument development, evidence use, cohesion, and language accuracy (Oh & Hsieh, 2025; Wang et al., 2024). Some research further suggests that ChatGPT may encourage students to consider alternative perspectives and develop stronger counterarguments, particularly when they interact with the tool through discussion-based or role-playing prompts (Ma et al., 2025). When used as a collaborative partner rather than a replacement for writing, ChatGPT may also promote reflection and critical thinking (Suh et al., 2025).

Despite these benefits, concerns have been raised about the use of ChatGPT in argumentative writing. Mai (2026) suggests that excessive reliance on AI-generated content may reduce students' critical engagement and lead to formulaic writing. In addition, ChatGPT may provide inaccurate, incomplete, or overly general responses, requiring students to verify information carefully (Chen et al., 2025). Researchers have also highlighted issues related to plagiarism, academic integrity, and the development of students' own rhetorical voice (Esmaeil

et al., 2023). These findings suggest that the effectiveness of ChatGPT depends largely on how critically and responsibly students use the tool.

Although previous studies have reported students' perceptions of ChatGPT in argumentative writing, existing research has primarily focused on the perceived benefits and challenges of the tool. For example, Esmaeil et al. (2023) found that students viewed ChatGPT as useful for idea generation, guidance, and writing support, while also expressing concerns about dependency, plagiarism, and reduced critical thinking. There is still relatively limited research about how EFL students actually use the tool while writing. To be more specific, it is unclear how students use ChatGPT to develop arguments, evaluate its responses, revise their essays, and check the accuracy of information. In addition, issues such as prompting skills, critical evaluation of AI-generated content, and the possibility of over-reliance have not been fully examined. Therefore, this study explores how intermediate-level EFL students use ChatGPT to support their argumentative essay writing and how they perceive its role in the writing process.

3. Methodology

3.1. Settings and participants

This study was conducted in an EFL context at a university, focusing on intermediate-level English majors. The participants were ten students, purposively selected based on their enrollment in a writing-intensive course and their experience with argumentative essay writing. All participants had similar English proficiency levels (CEFR B1–B2) to ensure consistency in their engagement with the ChatGPT tool.

3.2. Data collection

Data were collected using a qualitative method to capture the participants' experiences and perceptions (Ellis & Hart, 2023). Semi-structured interviews were conducted to explore participants' perceptions of ChatGPT's usefulness, the challenges they encountered, and their reflections on the tool's role in supporting their argumentative writing (Karatsareas, 2022).

3.3. Data analysis

All collected data, including interview transcripts, were analyzed using thematic analysis. The analysis focused on identifying patterns related to how students used ChatGPT to generate ideas, organize arguments, and incorporate counterarguments and evidence. The data were analyzed using thematic analysis. Interview recordings were first transcribed with the support of TurboScribe transcription software, and the transcripts were then checked with the original audio recordings to ensure accuracy.

The researchers generated initial codes, and grouped similar codes into major themes related to students' use of ChatGPT, such as idea generation, argument development, feedback use, prompting strategies, and concerns about over-reliance. To ensure the trustworthiness of the findings, both authors reviewed the coding and discussed any differences until they reached agreement (Cole, 2023). An expert in translation also reviewed the translated scripts. In addition, member checking was conducted to ensure the accuracy of the translations (Sahakyan, 2023).

4. Results

The interview data showed that students had both positive and cautious perceptions toward using ChatGPT in argumentative essay writing. Overall, they did not see ChatGPT as a replacement for their own thinking. Instead, they viewed it as a helpful tool that supported

different stages of writing, especially idea generation, developing arguments, revising, and improving language. Students also recognized some challenges, such as incorrect information, the risk of over-reliance, ethical concerns, and difficulties in writing effective prompts.

4.1. Strengthening arguments with ideas and evidence

Many participants reported that ChatGPT was particularly useful during the planning stage of argumentative writing. Students often described having difficulty generating ideas, especially when they were unfamiliar with the topic or could only think of one side of an issue. In these situations, ChatGPT helped them explore different perspectives, generate supporting details, and develop more balanced arguments.

Several students explained that ChatGPT provided multiple viewpoints rather than a single answer, allowing them to compare ideas before deciding which ones to include in their essays.

"It doesn't just give one answer, but multiple possible angles, so I can compare and choose the ones that fit my thinking" (P1).

Similarly, P3 explained that ChatGPT helped expand ideas when initial arguments were limited.

"Sometimes I only have one or two simple ideas, and I feel that they are not strong or diverse enough to develop into a full essay. So I use ChatGPT to generate more ideas or suggest different perspectives" (P3).

These comments suggest that students viewed ChatGPT as a brainstorming tool that broadened their thinking and helped them develop stronger arguments.

Another benefit frequently mentioned by participants was ChatGPT's ability to provide counterarguments. Students noted that argumentative writing requires considering different viewpoints, but they often focused only on their own position. ChatGPT helped address this issue by presenting alternative perspectives.

"It often provides both sides of an argument, including possible counterarguments, which helps me think more critically and avoid having a one-sided essay" (P3).

For some students, ChatGPT also reduced the pressure of getting started. Instead of facing a blank page, they could use AI-generated suggestions as a starting point for developing their own ideas.

"If I don't know how to start my essay or if I feel that my ideas are too limited, I ask ChatGPT to generate some initial ideas or give simple examples. This helps me reduce the pressure of starting" (P5).

Likewise, P9 highlighted the efficiency of receiving multiple ideas at once.

"It can provide multiple ideas at once, which saves time and helps me compare different options before choosing the most suitable ones" (P9).

Despite these benefits, participants emphasized that they did not simply copy ChatGPT's responses. Instead, they selected, modified, and combined AI-generated ideas with their own thinking.

"I usually don't take all the ideas from ChatGPT directly. Instead, I read through them and choose the ones that I think are relevant or suitable for my essay. Sometimes, I also combine its ideas with my own to create better arguments" (P6).

4.2. Developing evaluation through information verification

Although participants found ChatGPT useful, many emphasized that its responses should not be accepted without careful evaluation. Students were aware that ChatGPT could sometimes provide inaccurate, incomplete, or overly general information. As a result, they described a process of assessing AI-generated suggestions before deciding whether to use them in their essays.

Several participants explained that they did not simply copy ChatGPT's responses but actively evaluated their relevance and quality. For example, P1 stated:

> "I don't just copy its ideas. I usually read them, evaluate them, and then decide which ones are relevant to my argument" (P1).

A similar view was expressed by P10:

> "I also try to evaluate its suggestions instead of accepting them automatically" (P10).

These responses suggest that students maintained control over the writing process and treated ChatGPT as a source of suggestions rather than a source of final answers. Before incorporating AI-generated content into their essays, they considered whether the information was relevant, logical, and appropriate for their arguments.

Many reported that checking evidence, examples, and factual claims through other sources before using them in their writing is essential.

As P1 explained:

"I don't fully trust ChatGPT, especially when it provides evidence or examples. Sometimes the information is not accurate, so I always check external sources like Google or news websites" (P1).

Similarly, P3 noted:

> "For important ideas, critical thinking, or evidence, I still prefer to use my own thinking or search for information from reliable sources like Google or academic websites" (P3).

These comments indicate that participants were aware of the limitations of AI-generated information and recognized the importance of using reliable sources. Rather than treating ChatGPT as an authority, they used it as a starting point and then verified important information independently.

Interestingly, some students felt that this process encouraged them to become more critical when working with information. Because they knew that ChatGPT could make mistakes, they became more cautious when selecting evidence and supporting details for their arguments. In this sense, ChatGPT not only supported writing but also encouraged students to evaluate, question, and verify information more carefully.

Overall, participants reported that using ChatGPT involved more than simply receiving information. It required them to evaluate the quality of AI-generated responses, decide which suggestions were useful, and verify information through external sources before incorporating it into their writing.

4.3. Supporting revision through feedback and language improvement

Another benefit mentioned by participants was the use of ChatGPT during the revision stage. Many students reported using the tool after completing a first draft to receive feedback on grammar, vocabulary, sentence structure, academic tone, coherence, and overall essay

organization. For several participants, this was one of the most valuable ways ChatGPT supported their writing.

Some students explained that the quality of feedback improved when they provided specific criteria. For example, P2 shared:

> "After I finish writing my essay, I usually input my writing together with the rubric or scoring criteria, and I ask ChatGPT to evaluate my essay based on those criteria" (P2).

Similarly, P7 described assigning ChatGPT a specific role when requesting feedback:

> "I assign ChatGPT a role, such as an IELTS examiner or a lecturer, and include specific criteria like coherence, vocabulary, grammar, and task response. When I do this, the feedback becomes much more detailed, structured, and relevant to my needs" (P7).

These comments suggest that students used ChatGPT not only to identify problems in their writing but also to obtain more targeted feedback that aligned with assessment expectations.

Participants particularly valued feedback related to language use. Several students reported that ChatGPT helped them identify grammar and sentence structure errors that they often overlooked when revising independently.

As P4 explained:

> "After I finish writing my essay, I use ChatGPT to check grammar, spelling, and sentence structure. It helps me identify many small mistakes that I cannot notice by myself" (P4).

In addition to correcting errors, ChatGPT also helped students improve the academic quality of their writing. P6 noted:

> "Sometimes my writing is too informal, and ChatGPT suggests more formal expressions that are more suitable for academic writing or IELTS essays" (P6).

Likewise, P4 highlighted the role of ChatGPT in vocabulary improvement:

> "One of my biggest problems in writing is repetition. I often use the same words again and again without realizing it. ChatGPT helps me replace those words with synonyms and suggests more varied expressions" (P4).

These responses indicate that students viewed ChatGPT as a useful tool for improving language accuracy, vocabulary variety, and academic style.

Beyond language correction, several participants felt that ChatGPT helped them better understand their weaknesses as writers. Rather than simply providing corrections, the tool sometimes encouraged reflection on recurring problems.

For example, P1 stated:

> "One important experience I had is that ChatGPT helps me become more aware of my weaknesses. For example, I realized that I often write unclear topic sentences or repeat the same vocabulary" (P1).

Similarly, P5 appreciated the explanations provided by the tool:

> "One thing I find particularly useful is that ChatGPT not only corrects the mistakes but also explains why they are wrong. This helps me understand my errors more deeply and avoid repeating them in future writing" (P5).

These comments suggest that students valued feedback that supported learning rather than simple error correction.

Participants also reported using ChatGPT to improve idea development, cohesion, and essay organization. According to P10:

> "ChatGPT helps me understand how to structure an argumentative essay more clearly. For example, it shows me how to write a clearer introduction, how to develop body paragraphs with better topic sentences and supporting ideas, and how to write a more effective conclusion" (P10).

Likewise, P5 explained:

"Before using ChatGPT, I sometimes confused counterarguments and rebuttals, and my ideas were not clearly structured. ChatGPT helps me by suggesting supporting ideas, giving examples, and showing different ways to present arguments more effectively" (P5).

These responses indicate that ChatGPT supported not only linguistic accuracy but also students' understanding of how argumentative essays should be organized and developed.

4.4. Concerns about over-reliance, ethical use, and prompting skills

Although participants generally viewed ChatGPT positively, they also expressed concerns about its potential drawbacks. The most frequently discussed issue was over-reliance. Several students worried that depending too heavily on ChatGPT, particularly during idea generation, could reduce their ability to think independently and develop arguments on their own. Another issue frequently mentioned by participants was the need to verify information. Students recognized that although ChatGPT could generate convincing responses, the information was not always accurate.

Some participants reflected on how their use of ChatGPT changed over time. For example, P8 explained that after frequently relying on ChatGPT for brainstorming, they became aware of their growing dependence on the tool and intentionally adjusted their writing process.

> "At the beginning, I used ChatGPT quite frequently, especially in the brainstorming stage, because it was very easy to generate ideas quickly. However, after using it for some time, I realized that I was becoming too dependent on it" (P8).

As a result, P8 reported writing independently first and using ChatGPT mainly during the revision stage.

> "Now, I try to write my essay by myself first, without using ChatGPT in the early stages. Only after that do I use ChatGPT, mainly in the revision stage" (P8).

Similar concerns were raised by other participants. Some believed that excessive use of ChatGPT could weaken students' reasoning and idea-generation abilities.

> "If we depend on it for everything, especially for generating ideas, we may lose the ability to think independently" (P6).

> "If we rely on it too much, especially for generating ideas or writing entire essays, it can make us lazy and reduce our ability to think independently" (P10).

These comments suggest that students were aware of the need to maintain their own role in the writing process rather than allowing ChatGPT to do the thinking for them.

Another issue discussed by participants was the ethical use of ChatGPT. Students generally agreed that the tool should support learning rather than replace their own work. Many emphasized the importance of maintaining authorship and ensuring that the final essay reflected their own ideas and understanding.

For example, P5 explained that they did not use ChatGPT responses directly but instead adapted them to fit their own arguments.

> "I usually read the ideas it suggests, then select or adapt the ones that fit my understanding instead of copying them directly. In this way, I feel that I can still maintain my own voice in writing" (P5).

Likewise, P8 emphasized the importance of seeing ChatGPT as a learning resource.

> "I try to limit my usage and use ChatGPT more as a learning tool rather than a shortcut" (P8).

These responses indicate that participants were conscious of the ethical challenges associated with AI-assisted writing and attempted to use the tool responsibly.

A third concern involved prompting skills. Several students explained that the usefulness of ChatGPT depended heavily on the quality of the prompts they provided. Participants noted that vague prompts often produced generic responses, whereas detailed prompts resulted in more relevant and useful feedback.

As P2 explained:

> "When I write a clear and detailed prompt, the feedback is very useful. But when my prompt is too general, the feedback becomes vague and not helpful. So I think prompt-writing is a very important skill" (P2).

Similarly, P7 highlighted the importance of providing context and specific instructions when seeking feedback.

> "When my prompt is clear, specific, and includes context, the feedback is very useful and even quite similar to teacher feedback" (P7).

Some participants also described that they often needed to revise their prompts and ask follow-up questions to obtain more meaningful responses.

> "Sometimes the feedback is too general, especially when my prompt is not clear or detailed enough. In those cases, I need to ask follow-up questions or refine my prompt to get better answers" (P5).

5. Discussion

5.1. Strengthening arguments with ideas and evidence

A key finding of this study is that students viewed ChatGPT as a useful tool during the planning stage of argumentative writing. Many participants reported using ChatGPT when they had difficulty generating ideas, lacked background knowledge, or did not know how to begin an essay. As shown in the interview data, students emphasized ChatGPT's ability to provide multiple perspectives, supporting details, examples, and counterarguments. Rather than accepting a single response, they often compared different suggestions and selected those that best matched their own viewpoints. This finding suggests that students used ChatGPT not simply to obtain content but to expand and develop their ideas before writing.

This is consistent with Esmaeil et al. (2023) and Ho et al. (2024), who argued that ChatGPT can support idea generation, outline preparation, and content development in argumentative writing. Similarly, Darmawansah et al. (2024) found that ChatGPT-supported argumentation helped students strengthen their arguments through reasoning, feedback, and counterarguments. The present study supports these findings and further shows how students personally experienced this support. For many participants, ChatGPT reduced the difficulty of getting started and helped them explore different sides of an issue. This is important in argumentative writing because students are expected to consider diverse perspectives before developing their own position.

5.2. Developing evaluation through information verification

Another finding of this study is that students did not accept ChatGPT's responses immediately. Although participants generally found the tool helpful, they emphasized the importance of evaluating its suggestions before using them in their essays. Several students reported reading, comparing, selecting, adapting, or even rejecting ChatGPT-generated responses. Many also stated that they checked evidence and information using Google, news websites, or academic sources. These responses show that students were aware of the limitations of AI-generated content and tried to use the tool critically.

This result supports Chen et al. (2025)'s argument that the value of ChatGPT depends on how students interact with it. Rather than using ChatGPT passively, participants in this study engaged in a process of evaluation and verification. Interestingly, awareness of ChatGPT's limitations appeared to make some students more cautious when selecting information. As a result, using ChatGPT may encourage students to think more carefully about the relevance and reliability of information before including it in their writing. This indiates that ChatGPT can support the development of evaluative judgment when students are aware that its responses are not always accurate.

5.3. Supporting revision through feedback and language improvement

Qualitative data also showed that students used ChatGPT most frequently during the revision stage. Participants often described using the tool after completing a first draft to receive feedback on grammar, vocabulary, sentence structure, academic tone, coherence, and essay organization. Several students also reported providing rubrics or assigning specific roles, such as IELTS examiner or lecturer, to obtain more focused feedback. These practices indicate that students actively guided the feedback process to meet their own writing needs.

This finding is in line with Oh and Hsieh (2025), who found that ChatGPT can provide immediate feedback on both language and argumentative features. Similarly, Pratama et al. (2025) reported that students viewed AI-generated feedback positively because it was accessible and responsive. Consistent with these studies, participants in the present study valued ChatGPT because it allowed them to revise repeatedly and receive feedback whenever they needed it. More importantly, students reported that ChatGPT helped them identify recurring weaknesses, understand why certain errors occurred, and improve both language use and argument development. This suggests that ChatGPT can support not only revision but also students' awareness of their own writing strengths and weaknesses.

5.4. Concerns about over-reliance, ethical use, and prompting skills

However, students also reported several concerns about using ChatGPT. The most common concern was over-reliance. Several participants worried that frequent use of ChatGPT, particularly for idea generation, could reduce their ability to think independently. Some

students even described changing their writing habits after realizing that they had become too dependent on the tool. Instead of using ChatGPT from the beginning, they started generating ideas on their own and used the tool mainly for revision.

This finding is consistent with Mai (2026), who found that excessive reliance on ChatGPT may result in formulaic writing and lower levels of critical engagement. Similarly, Esmaeil et al. (2023) reported concerns that dependence on ChatGPT could weaken students' critical thinking skills. The findings of the present study support these concerns. At the same time, they show that some students were aware of this risk and attempted to use ChatGPT in a more balanced way. Rather than replacing their own thinking, they viewed ChatGPT as a tool that should support the writing process.

Students also emphasized the importance of writing effective prompts. Many participants explained that the quality of ChatGPT's responses depended heavily on the quality of the prompts they provided. Detailed prompts usually resulted in more useful and relevant feedback, while vague prompts often led to general or less helpful responses.

This result supports Ma et al. (2025), who emphasized the role of carefully designed prompts in obtaining useful support for argumentative writing. The findings of the present study suggest that prompting should be viewed as an important part of AI literacy. Students need to know how to provide context, specify their needs, ask follow-up questions, and refine their prompts when necessary. Therefore, if ChatGPT is to be integrated into EFL writing instruction, teachers should provide guidance not only on how to use AI tools but also on how to interact with them effectively.

6. Conclusion

This study examined how intermediate-level EFL students used ChatGPT to support their argumentative essay writing. The findings suggest that ChatGPT can support different stages of the writing process, particularly idea generation, argument development, and revision. Participants also reported using ChatGPT to explore alternative perspectives, develop counterarguments, and improve language use. Importantly, many students described evaluating and adapting AI-generated responses rather than accepting them directly, suggesting that ChatGPT can support critical engagement when used appropriately. However, the study also highlights several concerns, including over-reliance, ethical issues, and limited prompting literacy. Students may benefit less from ChatGPT if they use it passively or depend on it to replace their own thinking. Therefore, ChatGPT should be integrated into EFL writing instruction with clear guidance on responsible use, source verification, and effective prompting.

Although this study contributes to the understanding of students' experiences with ChatGPT in argumentative writing, there are still some limitations. The study involved a relatively small group of students from a single educational context and relied primarily on interview data. Future research could build on these findings by examining a larger and more diverse sample of learners. In particular, experimental or longitudinal studies could investigate whether and to what extent ChatGPT use leads to measurable improvements in argumentative writing quality over time.

Acknowledgments

The authors would like to thank all participants for their time and valuable contributions to this study. Their participation was essential to the completion of this research. We also sincerely

appreciate the anonymous reviewers for their insightful comments and constructive feedback, which greatly helped improve the quality and clarity of this paper.

#89 EFL TEACHERS' PERCEPTIONS OF AI-SUPPORTED AND DIGITAL TECHNOLOGIES IN IELTS TEACHING FOR HIGH-QUALITY STUDENTS

Thai, Ho-Van[1]

Abstract

AI and Digital technologies have been taking a crucial focus in the English language learning in higher education in high-stakes preparation institutions like IELTS. While there are many international studies that consider the role of technology in facilitating language learning, fewer have included examining how Vietnamese EFL teachers perceive the factors influencing their adoption of digital and AI-driven tools in teaching high-quality students to take the IELTS. This research investigates what influences the adoption of such technologies by teachers in Vietnamese higher education institutions which provide high-quality programmes. A mixed-method approach - survey responses from 50 IELTS lecturers together with interviews were utilised to elicit more detailed findings. Results indicate that teachers' willingness to use AI-supported and digital technologies is driven by five main factors: pedagogic beliefs, technological knowledge and digital competence, personal interest and perceived usefulness, time constraints and workload, as well as institutional culture, infrastructure, and policy support. Despite the gains that teachers cited that AI enhances performance such as automatic feedback, enhanced learner engagement, accelerated test-prep, teachers recognised concern about AI effectiveness and reliability and students' dependence upon AI tools and possible inconsistencies with IELTS assessment criteria. These findings highlight the necessity of systematic AI literacy training, clearer institutional guidelines & implementation of digital pedagogy principles in the curriculum and policy framework for the more critical and potent use of AI-supported technologies in IELTS-directed instruction for students.

***Keywords*:** EFL, Artificial Intelligence, perceptions of AI, IELTS, high-quality

1. Introduction

1.1. Background

The rapid evolution of generative artificial intelligence (AI) and specialized digital applications has radically reshaped the landscape of higher education globally, and English as a Foreign Language (EFL) instruction is no exception (Davis, 2024; Kamalov et al., 2023). Within the context of high-stakes language assessment, particularly the International English Language Testing System (IELTS), digital and AI-driven tools have transitioned from peripheral supplementary materials to core pedagogical infrastructure. In Vietnamese higher education, this technological shift intersects with institutional efforts to elevate academic standards through the implementation of "high-quality" academic programs. These specialized programs explicitly demand superior English proficiency from undergraduates, frequently utilizing ambitious IELTS band scores (ranging from 6.5 to 7.5 or higher) as strict benchmarks for global academic integration and graduation clearance. Consequently, tertiary EFL lecturers

[1]*College of Foreign Economic Relations, Ho Chi Minh City, Vietnam; Email: hvthai@cofer.edu.vn*

must navigate the intricate demands of high-stakes exam preparation while simultaneously integrating complex digital ecosystems into their daily instructional routines.

1.2. Statement of the problem

While technology acceptance in EFL is a widely researched domain, the integration of AI tools in specialized, high-stakes testing contexts presents a unique, underexplored pedagogical crisis. IELTS preparation is inherently challenging due to its rigorous assessment rubrics, which require candidates to demonstrate advanced cognitive skills and highly structured academic writing. The core problem emerges when these generalized AI tools intersect with highly pragmatic learner cohorts, specifically, logistics-majored students enrolled in high-quality English programs.

Unlike traditional language or business English majors, logistics students are rigorously trained to prioritize operational efficiency, problem-solving, and task completion. When preparing for the IELTS, this pragmatic mindset often drives them to utilize generative AI not as a cognitive scaffold, but as an academic shortcut to outsource language production, creating a severe algorithmic dependency cycle. Despite the growing ubiquity of automated writing evaluation and generative AI, there is a critical empirical gap regarding how Vietnamese EFL lecturers perceive and manage this specific crisis. Educators are currently operating in an institutional policy vacuum, struggling to balance the efficiency gains of AI with the urgent need to mitigate student overreliance and maintain alignment with strict IELTS band descriptors. The inquiry is guided by the following research questions:

RQ1. *What are the primary factors influencing EFL teachers' perceptions of AI-supported technologies in IELTS teaching?*

RQ2. *How do institutional constraints and the specific pragmatic learning behaviors of non-language majors impact teachers' instructional agency regarding AI integration?*

Drawing upon the Technology Acceptance Model (TAM) and the Technological Pedagogical Content Knowledge (TPACK) framework, this study proposes the following quantitative hypotheses:

H1. *Perceived usefulness (PU) and TPACK positively influence teachers' willingness to integrate AI-supported tools in IELTS preparation.*

H2. *Time constraints, heavy workload, and lack of institutional policy support negatively moderate the pedagogical integration of AI-driven tools.*

H3. *Teachers' concerns regarding AI reliability and student algorithmic dependence negatively impact their unconditional acceptance of generative AI in high-stakes writing instruction.*

1.4. Delimitations

To ensure empirical depth and contextual relevance, this study is delimited in its scope. Geographically and institutionally, the research targets higher education institutions located in Ho Chi Minh City, Vietnam. Demographically, the participant pool is limited to 50 tertiary EFL lecturers explicitly tasked with teaching IELTS preparation courses. Furthermore, the instructional context is confined to high-quality undergraduate programs, specifically targeting cohorts of logistics-majored students learning English for specific professional and academic purposes. This study explicitly excludes English linguistics majors.

2. Literature Review

2.1. Theoretical perspectives on AI-supported instruction in IELTS teaching

The growing presence of AI in educational settings has prompted renewed attention to how emerging technologies shape teaching practices (Dimitriadou & Lanitis, 2023). In English language education, AI-supported instruction refers to the use of intelligent systems, such as automated feedback tools, intelligent tutoring applications, and generative language models, to support learners during the language acquisition process (Liu et al., 2025).

Understanding teachers' engagement with such tools in high-stakes testing contexts like IELTS requires a theoretically grounded perspective that recognizes teaching as a cognitively and socially situated activity (Poquet, 2024). Teacher cognition theory provides a useful foundation for examining how teachers interpret and respond to instructional innovations, asserting that teachers' beliefs, perceptions, and prior experiences strongly influence classroom decision-making and instructional behavior (Bakshi, 2021). The introduction of AI into IELTS instruction, therefore, does not lead to uniform pedagogical change; rather, it is mediated by teachers' perceptions of AI regarding its instructional value, risks, and legitimacy (Wu et al., 2026).

In addition, the TAM suggests that individuals' adoption of new technologies is influenced by perceived usefulness and perceived ease of use (Liesa-Orús et al., 2023). Within high-stakes preparation contexts, these perceptions are closely linked to pedagogical beliefs and professional identity (Suarez & McGrath, 2022). Complementing these perspectives, Technological Pedagogical Content Knowledge (TPACK) theory emphasizes that meaningful technology integration depends on teachers' ability to align technological knowledge with pedagogical strategies and subject matter expertise, specifically the rigid evaluation criteria of the IELTS band descriptors (Zhang & Li, 2025).

2.2. Teachers' perceptions of AI-supported in IELTS teaching

Teachers' perceptions of AI-supported tools represent a critical cognitive driver that shapes instructional readiness (Wu et al., 2026). In high-stakes IELTS training, teachers exhibit a complex mixture of optimism and caution. Educators often perceive AI tools as highly useful for enhancing feedback quality, supporting continuous drafting, and managing the heavy instructional workload associated with grading writing and speaking components (An et al., 2022; Bower et al., 2024). When AI is perceived as an administrative asset that improves performance, teachers are more likely to integrate it as a resource that extends their professional role (Wu et al., 2026).

On the other hand, serious concerns persist regarding the reliability and alignment of AI feedback with official IELTS evaluation criteria (Li & Huang, 2025). Anxiety regarding academic integrity, potential algorithmic bias, and the fear of reducing students' critical thinking through overreliance often diminishes teachers' acceptance (Gustilo et al., 2024; Li & Huang, 2025). Therefore, teachers' perception does not function as a simple binary attitude but as an evaluative interpretive framework through which they negotiate the boundaries between automated efficiency and pedagogical validity (Azis & Numan, 2026).

2.3. Professional development and teacher AI competence

Professional development (PD) serves as the primary capability-building mechanism through which teachers construct technological knowledge, negotiate professional norms, and develop shared digital pedagogy principles within communities of practice (Chiu et al., 2025;

Dlamini et al., 2024). In the rapidly evolving domain of AI, traditional technical training that focuses solely on software proficiency is insufficient (Azis & Numan, 2026).

Effective PD must address both pedagogical implementation and ethical awareness, equipping IELTS instructors with the critical literacy needed to distinguish accurate automated outputs from algorithmic errors (Mouta et al., 2025). Without continuous institutional learning support, teachers' positive perceptions may fail to manifest as actual classroom innovation. PD effectively bridges the gap between perception and practice by enhancing instructional competence and strengthening teachers' confidence to exercise professional agency when integrating AI tools into high-stakes test environments (Wu et al., 2026).

2.4. Institutional and ethical support in higher education

Institutional and ethical support (IES) reflects the macro-environmental conditions, including organizational norms, structural infrastructure, and explicit policy frameworks, that regulate and legitimize educational innovations (Balzano et al., 2024). According to institutional theory, the enactment of individual capacity is highly contingent upon the stability of organizational structures (Wu et al., 2026).

When universities provide clear, explicit guidelines regarding the ethical boundaries of generative AI and intellectual property, teachers experience lower perceived risks and higher professional safety (Holmes & Porayska-Pomsta, 2023). Conversely, ambiguous or weak institutional governance forces instructors to rely entirely on personal risk management, which can severely constrain the deployment of innovative practices (Mouta et al., 2025). In early technological adoption phases, IES can function as a crucial compensatory or stabilizing structure that reduces variability driven by differences in individual teacher preparedness (Wu et al., 2026).

2.5. Pedagogical integration of AI and washback on IELTS rubrics

Pedagogical integration (PIAI) denotes the extent to which digital and AI-driven tools are purposefully embedded into instructional designs, daily classroom interactions, and assessment paradigms (Wu et al., 2026). In an exam-driven curriculum like IELTS, integration is intensely dominated by the washback effect, the direct impact of testing formats on teaching methodologies (Latif & Wasim, 2022; Lei & Lei, 2025). Meaningful PIAI requires that automated evaluation tools accurately reflect the hyper-specific public band descriptors of the exam, including lexical resource, grammatical range, and coherence (Wu et al., 2026). Effective pedagogical integration occurs when AI functions as a scaffold for independent learner development, rather than a shortcut that automates language production. Achieving this balance requires constant professional calibration to ensure that computer-assisted assessment practices align with authentic human-scored language standards (Azis & Numan, 2026).

3. Methodology

3.1. Research design

This study used a convergent parallel mixed-methods design to investigate tertiary EFL lecturers' perceptions and experiences regarding AI integration. This design allowed quantitative survey data and qualitative interview narratives to be collected concurrently and analyzed iteratively, facilitating the triangulation of findings and enriching the interpretation of the factors affecting technology adoption (Abedi et al., 2024; Denny & Weckesser, 2022). The quantitative component mapped broad institutional and pedagogical trends using descriptive statistics, while the qualitative component captured the nuanced, context-dependent

reasoning underlying teachers' decisions to integrate, modify, or limit specific tools (Hall & Liebenberg, 2024).

3.2. Participants and Context

The participant sample comprised 50 tertiary EFL lecturers (N=50) actively teaching IELTS preparation modules within high-quality undergraduate tracks across higher education institutions in Ho Chi Minh City, Vietnam. Purposive sampling was applied to guarantee that all respondents possessed a minimum of two years of direct experience preparing students for high-stakes graduation and professional language benchmarks.The sample exhibited a diverse range of instructional experience (from early-career lecturers to senior faculty members) and institutional profiles, with all participants holding postgraduate degrees (Master's or Ph.D. level). To protect participant confidentiality, all institutional and individual identifiers were fully anonymized through the use of alphanumeric codes and generic placeholders.

3.3. Instruments and data analysis

Quantitative data were gathered using a closed-ended questionnaire featuring a 5-point Likert scale (ranging from 1 = Strongly Disagree to 5 = Strongly Agree). The measurement items were adapted from established technology adoption instruments (Richter & Richter, 2024) and tailored to the operational realities of high-stakes IELTS teaching. The survey measured five core dimensions: pedagogic beliefs, technological knowledge, personal interest/usefulness, time constraints, and institutional culture. Quantitative analysis was executed using descriptive statistical software to compute means (M), standard deviations (SD), and standard errors. Qualitative insights were elicited via semi-structured, semi-formal interviews with a subset of ten participants (n=10) who volunteered during the survey phase. The interview protocol focused on participants' specific instructional adjustments, experiences with algorithmic discrepancies, and strategies for managing student dependence. All qualitative audio data were transcribed verbatim and analyzed using inductive thematic analysis (Braun & Clarke, 2021). This involved generating initial open codes, grouping codes into stable conceptual categories, and extracting overarching thematic dimensions to triangulate the quantitative findings.

4. Results

The mixed-methods analysis revealed that the pedagogical integration of AI-supported technologies in high-stakes IELTS preparation is not a linear adoption process. Instead, it is driven by a complex matrix of internal teacher cognitions *(beliefs, agency, and technological competence)* and external systemic constraints *(time, workload, and institutional policy).*

4.1. Quantitative Survey Findings

The quantitative data derived from the 50 surveyed EFL lecturers indicated varied levels of agreement across the major operational factors affecting technological adoption. The descriptive statistics for the five core dimensions are presented in Table 1.

Table 1

Factors influencing AI and Digital technology

Dimension	N	Mean	Std. Deviation	Std. Error Mean
Factor 1: Pedagogic beliefs & Alignment	50	3.84	0.62	.08
Factor 2: Technological knowledge & Competence	50	3.42	0.78	.11

Factor 3: Personal interest & Perceived usefulness	50	4.12	0.55	.07
Factor 4: Availability of time & Manageable workload	50	2.15	0.84	.12
Factor 5: Institutional culture & Policy support	50	2.89	0.91	.13

*Scores are based on a 5-point Likert scale (1 = Strongly Disagree, 5 = Strongly Agree).
